December 3, 2025

## Abstract

This paper develops a model to analyze the effects of AI advancements on human capital investment and their impact on aggregate and distributional outcomes in the economy. We construct an incomplete markets economy with endogenous asset accumulation and general equilibrium, where households decide on human capital investment and labor supply. Anticipating near-term AI advancements that will alter skill premiums, we analyze the transition dynamics toward a new steady state. Our findings reveal that human capital responses to AI amplify its positive effects on aggregate output and consumption, mitigate the AI-induced rise in precautionary savings, and stabilize the adjustments in wages and asset returns. Furthermore, while AI-driven human capital adjustments increase inequalities in income, earnings, and consumption, they unexpectedly reduce wealth inequality.

**Keywords:** AI, Job Polarization, Human Capital, Inequality

## <sup>1</sup> 1 Introduction

<sup>2</sup> A defining feature of recent AI advancements is their ability to perform complex,  
<sup>3</sup> cognitive, non-routine tasks – capacities that once required substantial education  
<sup>4</sup> and expertise. This fundamental difference sets AI apart from earlier waves of au-  
<sup>5</sup> tomation or computerization, which primarily replaced manual or routine labor.<sup>1</sup> In  
<sup>6</sup> this paper, we make a central assumption – supported by a growing body of evidence  
<sup>7</sup> – that AI adoption reduces the premium for middle-level skills while increasing the  
<sup>8</sup> value of high-level expertise. Based on this assumption, we develop a model to study  
<sup>9</sup> the effects of AI advancements on human capital investment and their subsequent  
<sup>10</sup> impact on aggregate and distributional outcomes of the economy.

<sup>11</sup> Recent labor market data highlight the disproportionate impact of AI on entry-  
<sup>12</sup> level employment opportunities. Bloomberg (Bloomberg, 2025) reports that, in  
<sup>13</sup> the words of Matt Sigelman, president of the Burning Glass Institute, “Demand  
<sup>14</sup> for junior hires in many college-level roles is already declining, even as demand  
<sup>15</sup> for experienced hires in the same jobs is on the rise.” According to Revelio Labs  
<sup>16</sup> (Revelio Labs, 2025), postings for entry-level jobs in the US declined by about  
<sup>17</sup> 35% since January 2023, with roles more exposed to AI experiencing even steeper  
<sup>18</sup> reductions.

<sup>19</sup> Recent experimental evidence reviewed by Calvino *et al.*, (2025) shows that  
<sup>20</sup> workers’ productivity gains from AI depend on their skill levels and experience. On  
<sup>21</sup> simpler tasks where AI performs well, the technology can narrow the productivity  
<sup>22</sup> gap between experienced and less experienced workers. However, for more complex  
<sup>23</sup> tasks that AI cannot yet perform effectively, those with greater digital proficiency  
<sup>24</sup> or task-specific experience achieve higher productivity gains, as successful use of AI  
<sup>25</sup> in these settings requires more advanced skills and experience that involves under-  
<sup>26</sup> standing AI’s capabilities and limitations.

<sup>27</sup> Firm-level evidence reveals similar patterns. Aghion *et al.*, (2019) documents  
<sup>28</sup> that the average worker in low-skilled occupations receives a significant wage pre-  
<sup>29</sup> mium when employed by a more innovative firm. Souza (2025) finds that the adop-  
<sup>30</sup> tion of AI in Brazilian firms increases employment for low-skilled production workers  
<sup>31</sup> but reduces employment and wages for middle-wage office workers. Asam and Heller  
<sup>32</sup> (2025) report that GitHub Copilot enables software startups to raise initial funding  
<sup>33</sup> 19% faster with 20% fewer developers, and that these productivity gains dispropor-  
<sup>34</sup> tionately benefit startups with more experienced founders.

<sup>35</sup> In anticipation of these changes, households are likely to adjust their human cap-  
<sup>36</sup> ital investments. A 2022 report by Higher Education Strategy Associates finds that  
<sup>37</sup> following decades of growth, dropping student enrollment in higher education has

---

<sup>1</sup>For example, AI tools in medical diagnostics now assist radiologists in analyzing medical images, potentially reducing demand for entry-level radiologists while simultaneously increasing the productivity of senior professionals.

38 become a major trend in the Global North (Higher Education Strategy Associates,  
39 2022). In the U.S., the public across the political spectrum has increasingly lost  
40 confidence in the economic benefits of a college degree.<sup>2</sup>

41 On the other hand, demand for sector-based training and reskilling opportu-  
42 nities has been rising. The Oliver Wyman Forum's 2024 study (Oliver Wyman  
43 Forum, 2024) documents widespread and significant gaps between employees' desire  
44 for reskilling in generative AI and the opportunities their employers are willing to  
45 offer. The study estimates that, over the coming decade, billions of workers will  
46 need upskilling and millions may require complete reskilling.

47 This paper constructs an incomplete markets economy with endogenous asset  
48 accumulation and general equilibrium to study how AI's effects on skill premia  
49 interact with households' human capital investment, and their subsequent impact  
50 on aggregate and distributional outcomes of the economy.

51 We consider an economy with three sectors, each requiring low, middle, or high  
52 levels of skill (human capital) and exhibiting increasing labor productivity. House-  
53 holds can invest in human capital to move up to more productive sectors; without  
54 such investment, their skills depreciate, causing them to shift toward less produc-  
55 tive sectors over time. Human capital investment occurs at two levels: a basic level  
56 achievable while working, and a higher level that demands full-time commitment,  
57 such as pursuing higher education or reskilling training. Households face uninsur-  
58 able idiosyncratic productivity shocks, affecting both their labor productivity and  
59 the returns to human capital investment.

60 We model AI advancements as increasing the productivity for the low and high  
61 sectors but not for the middle sector so that the skill premium of the middle sector  
62 decreases and the skill premium of the high sector increases.

63 Using a two-period partial equilibrium model, we show that the effects of AI on  
64 skill premia discourage human capital investment for households in the low sector  
65 and encourage human capital investment for households in the middle sector, thereby  
66 increasing human capital inequality.

67 Human capital investment via full-timing training crowds out households' labor  
68 supply so that households in the low sector supplies more labor whereas households  
69 in the high sector supplies less labor, in response to the AI advancements.

70 We also investigate the interaction between human capital investment and saving.  
71 When households could adjust their human capital, the skill premium matters for  
72 their idiosyncratic risk exposure because when they move across sectors, their labor  
73 income is affected by the skill premium. As AI reduces the skill premium of the  
74 middle sector, households in the low sector has lower idiosyncratic risk exposure

---

<sup>2</sup>Pew Research Center reports that about half of Americans say having a college degree is less important today than it was 20 years ago in a survey conducted in 2023 (Pew Research Center, 2024). A 2022 study from Public Agenda (Public Agenda, 2022), a nonpartisan research organization, shows that young Americans without college degrees are most skeptical about the value of higher education.

75 and thus reduce their saving. Conversely, AI increases the skill premium of the  
76 high sector, households in the high sector has higher idiosyncratic risk exposure and  
77 thus increase their saving. AI's effect on saving of the middle-sector households is  
78 ambiguous.

79 At the economy level, the effects of AI advancements depend on the sectoral re-  
80 distribution of households and the general equilibrium effects via wage and capital  
81 return responses. We quantify these effects using a fully-fledged dynamic quanti-  
82 tative model that incorporates an infinite horizon, endogenous asset accumulation,  
83 and general equilibrium. The model is calibrated to reflect key features of the U.S.  
84 economy, capturing realistic household heterogeneity. The steady state distribution  
85 of human capital without AI advancements pins down the sectoral distribution of  
86 households. We then introduce fully anticipated AI advancements happening in the  
87 near future and study the transition dynamics from the current state of the economy  
88 to the eventual new steady state.

89 Our quantitative model demonstrates that AI induces a *voluntary job polarization*  
90 through both human capital investment and labor supply choices. A substan-  
91 tial share of middle-sector households voluntarily reallocate to either the low or  
92 high sectors in the new steady state via human capital adjustments. During the  
93 transition, human capital accumulation becomes increasingly concentrated among a  
94 smaller segment of the population, reflecting growing inequality in skill acquisition.  
95 In addition to these population shifts, labor supply dynamics further contribute to  
96 job polarization: many middle-sector households reduce their labor supply as they  
97 engage in full-time training to upskill more rapidly, while labor supply in the low  
98 sector rises more than in the high sector.

99 Building on these labor dynamics, our model examines how AI influences aggre-  
100 gate and distributional outcomes of the economy via its direct effects on sectoral  
101 productivity and via the endogenous response of human capital investment. To do  
102 so, we contrast transition dynamics between the benchmark model and a model with  
103 human capital fixed at the initial steady state (so that only the direct effect of AI  
104 is present).

105 Our findings reveal that human capital responses to AI amplify its positive effects  
106 on aggregate output and consumption, but mitigate its positive effect on employ-  
107 ment. While AI's direct effect on sectoral productivity reduces income and con-  
108 sumption inequalities, job polarization resulting from human capital adjustments  
109 reverses this effect and increases both inequalities.

110 Regarding households' saving, the indirect effect of AI through human capital  
111 adjustments has little impact on aggregate savings – both in terms of steady state  
112 and during the transition. However, these adjustments have a substantial impact on  
113 the distribution of wealth: while AI's direct effect increases wealth inequality, the  
114 indirect effect from human capital responses counteracts and partially offsets this

115 increase.

### 116 1.1 Related Literature

117 This paper relates to the literature on how technological change, including AI and  
118 robotics, drives job polarization and affects the demand and supply of labor. Studies  
119 find that rising employment in both high- and low-wage occupations—at the expense  
120 of middle-skill jobs—characterizes job polarization across the UK, US, and Western  
121 Europe (Goos and Manning, 2007; Autor and Dorn, 2013; Goos *et al.*, 2014). Robots  
122 and automation have also been shown to reduce employment and wages across US  
123 regions (Acemoglu and Restrepo, 2020), with automation-induced job losses and  
124 declining labor force participation especially concentrated among vulnerable workers  
125 in highly automated sectors (Lerch, 2021; Faber *et al.*, 2022).

126 Technological disruption also influences human capital accumulation. Faced with  
127 employment risks caused by automation, many affected workers invest in further  
128 education as a form of self-insurance, rather than relying solely on increases in the  
129 college wage premium (Atkin, 2016; Beaudry *et al.*, 2016). Consistent with this,  
130 Di Giacomo and Lerch (2023) and Dauth *et al.*, (2021) find that the adoption of  
131 industrial robots in the U.S. and Germany, respectively, has led to increased college  
132 and university enrollments.

133 Building on this largely empirical literature, our paper develops a model that  
134 explicitly allows for a trade-off between labor supply and human capital investment.  
135 In our framework, job polarization emerges as a voluntary response to AI advance-  
136 ments: households in the middle sector may choose to either downskill to the low  
137 sector or upskill to the high sector, while an increasing number of middle-sector  
138 households opt for full-time training to accelerate their upskilling.

139 The rise of AI and automation also plays a significant role in exacerbating gen-  
140 eral inequality, particularly through its impact on education and wealth distribution.  
141 Prettner and Strulik (2020) present a model showing that innovation-driven growth  
142 leads to an increasing proportion of college graduates, which in turn drives higher  
143 income and wealth inequality. As technology advances, workers with higher educa-  
144 tional attainment benefit disproportionately, widening the gap between those with  
145 and without advanced skills. Sachs and Kotlikoff (2012) also explore this dynamic,  
146 providing a model within an overlapping generations framework that examines the  
147 interaction between automation and education. They demonstrate how automation  
148 can further entrench inequality by favoring workers with higher levels of educa-  
149 tion, as those without adequate skills are more likely to be displaced or see their  
150 wages stagnate. This interaction between technological change and educational at-  
151tainment not only amplifies economic inequality but also perpetuates disparities in  
152 wealth across generations.

153 The rest of the paper is organized as follows. Section 2 describes the model

154 environment. Section 3 solves the household's problem using a two-period version  
 155 of the model. Section 4 solves the fully-fledged quantitative model and calibrates it  
 156 to fit key features of the U.S. economy, including employment rate, human capital  
 157 investment, and household heterogeneity. Section 5 incorporates AI into the quan-  
 158 titative model and examines its impacts on human capital adjustments. Section 6  
 159 analyzes the aggregate and distributional effects of AI. Section 7 concludes.

## 160 **2 Model Environment**

161 Time is discrete and infinite. There is a continuum of households. Each household  
 162 is endowed with one unit of indivisible labor and faces idiosyncratic productivity  
 163 shock,  $z$ , that follows an AR(1) process in logs:

$$\ln z' = \rho_z \ln z + \varepsilon_z, \varepsilon_z \stackrel{\text{iid}}{\sim} N(0, \sigma_z^2) \quad (1)$$

164 The asset market is incomplete following Aiyagari (1994), and the physical capital,  
 165  $a$ , is the only asset available to households to insure against this idiosyncratic risk.  
 166 Households can also invest in human capital,  $h$ , which allows them to work in sectors  
 167 with different human capital requirement.

### 168 *2.1 Production Technology*

169 The production technology in the economy is a constant-returns-to-scale Cobb-  
 170 Douglas production function:

$$F(K, L) = K^{1-\alpha} L^\alpha \quad (2)$$

171  $K$  represents the total physical capital accumulated by households, while  $L$  denotes  
 172 the total effective labor supplied by households, aggregated across three sectors: low,  
 173 middle, and high. The marginal products of capital and effective labor determine  
 174 the economy-wide wage rate,  $w$ , and interest rate,  $r$ .

175 These sectors differ in their technologies for converting labor into effective labor  
 176 units and in the levels of human capital required for employment. The middle sector  
 177 employs households with human capital above  $h_M$  and converts one unit of labor  
 178 to one effective labor unit. The high sector, requiring human capital above  $h_H$ ,  
 179 converts one unit of labor to  $1 + \lambda$  effective units, while the low sector, with no  
 180 human capital requirement, converts one unit into  $1 - \lambda$  effective units. This implies  
 181 a sectoral labor productivity  $x(h)$  that is a step function in human capital:

$$x(h) = \begin{cases} 1 - \lambda & \text{low sector if } h < h_M \\ 1 & \text{middle sector if } h_M < h < h_H \\ 1 + \lambda & \text{high sector if } h > h_H \end{cases} \quad (3)$$

<sup>182</sup> A household  $i$  who decides to work thus contributes  $z_i x(h_i)$  units of effective labor,  
<sup>183</sup> where  $z_i$  is his idiosyncratic productivity. Denote  $n_i \in \{0, 1\}$  as the indicator that  
<sup>184</sup> takes one if the household works and zero if the household does not. The aggregate  
<sup>185</sup> labor is

$$L = \int n_i z_i x(h_i) di, \quad (4)$$

<sup>186</sup> assuming perfect substitutability of effective labor across the three sectors.

## <sup>187</sup> 2.2 Household's Problem

<sup>188</sup> Households derive utility from consumption, incur disutility from labor and effort of  
<sup>189</sup> human capital investment. A household maximizes the expected lifetime utility by  
<sup>190</sup> optimally choosing consumption, saving, labor supply and human capital investment  
<sup>191</sup> each period, based on his idiosyncratic productivity shock  $z_t$ :

$$\max_{\{c_t, a_{t+1}, n_t, e_t\}_{t=0}^{\infty}} E_0 \left[ \sum_{t=0}^{\infty} \beta^t (\ln c_t - \chi_n n_t - \chi_e e_t) \right] \quad (5)$$

<sup>192</sup> where  $c_t$  represents consumption,  $a_{t+1}$  represents saving,  $n_t \in \{0, 1\}$  is labor supply,  
<sup>193</sup> and  $e_t$  is the effort of human capital investment.

<sup>194</sup> If a household decides to work in period  $t$ , he will be employed into the appropriate sector according to his human capital  $h_t$  and receive labor income  $w_t z_t x(h_t)$ .  
<sup>195</sup> The household's budget constraint is

$$c_t + a_{t+1} = n_t (w_t z_t x(h_t)) + (1 + r_t) a_t \quad (6)$$

$$c_t \geq 0 \text{ and } a_{t+1} \geq 0 \quad (7)$$

<sup>197</sup> We prohibit households from borrowing  $a_{t+1} \geq 0$  to simplify analysis.<sup>3</sup>

<sup>198</sup> Human capital investment can take three levels of effort:  $\{0, e_L, e_H\}$ . A non-  
<sup>199</sup> working household is free to choose any of the three effort levels but a working  
<sup>200</sup> household cannot devote the highest level of effort  $e_H$ , reflecting a trade-off between  
<sup>201</sup> working and human capital investment. Hence:

$$e_t \in \{0, e_L, (1 - n_t)e_H\}. \quad (8)$$

<sup>202</sup> Its contribution to next-period human capital is subject to the productivity shock:

$$h_{t+1} = z_t e_t + (1 - \delta) h_t \quad (9)$$

<sup>203</sup> where  $\delta$  is human capital's depreciation rate.

---

<sup>3</sup>According to Aiyagari (1994), a borrowing constraint is necessarily implied by present value budget balance and nonnegativity of consumption. Since the borrowing limit is not essential to our analysis, we set it to zero for simplicity.

<sup>204</sup> **3 Household Decisions in a Two-Period Model**

<sup>205</sup> In this section, we solve the household's problem with two periods to gain intuition.

<sup>206</sup> **Period-2 decisions** Households do not invest in human capital or physical capital  
<sup>207</sup> in the last period. The only relevant decision is whether to work.

<sup>208</sup> The household works  $n = 1$  if and only if  $z \geq \bar{z}(h, a)$ , with  $\bar{z}(h, a)$  defined as

$$\ln(w\bar{z}(h, a)x(h) + (1 + r)a) - \chi_n = \ln((1 + r)a) \quad (10)$$

<sup>209</sup> The household faces a trade-off between earning labor income and incurring the  
<sup>210</sup> disutility of working. Given the sector-specific productivity  $x(h)$  specified in (3),  
<sup>211</sup> the threshold for idiosyncratic productivity,  $\bar{z}(h, a)$ , takes on three possible values:

$$\bar{z}(h, a) = \begin{cases} \bar{z}(a)\frac{1}{1-\lambda} & \text{if } h < h_M \\ \bar{z}(a) & \text{if } h_M \leq h < h_H \\ \bar{z}(a)\frac{1}{1+\lambda} & \text{if } h > h_H \end{cases} \quad (11)$$

$$\text{where } \bar{z}(a) := \frac{(\exp(\chi_n) - 1)(1 + r)a}{w} \quad (12)$$

<sup>212</sup> Households with higher human capital is more likely to work, whereas households  
<sup>213</sup> with higher physical capital is less likely to work.

<sup>214</sup> **Period-1 decisions** In addition to labor supply, period-1 decisions include saving  
<sup>215</sup> and human capital investment, both of which are forward-looking and affected by  
<sup>216</sup> the idiosyncratic risk associated with the productivity shock  $z'$ . Our model also  
<sup>217</sup> features a trade-off between human capital investment and labor supply as a working  
<sup>218</sup> household cannot devote the highest level of effort  $e_H$  in human capital investment.  
<sup>219</sup> Therefore, human capital investment grants households the possibility of a discrete  
<sup>220</sup> wage hike in the future but may entail a wage loss in the current period.

<sup>221</sup> To see the implication of this trade-off and how it interacts with uninsured  
<sup>222</sup> idiosyncratic risk, we proceed in two steps. We first derive the period-1 decisions  
<sup>223</sup> without uncertainty by assuming that  $z'$  is known to the household at period 1 and  
<sup>224</sup>  $z'$  is such that the household will work in period 2. We then reintroduce uncertainty  
<sup>225</sup> in  $z'$  and compare the decision rules with the case without uncertainty.

<sup>226</sup> *3.1 Period-1 Labor Supply and Human Capital Investment*

<sup>227</sup> **3.1.1 Consumption and saving without uncertainty**

<sup>228</sup> The additive separability of household's utility implies that labor supply  $n$  and  
<sup>229</sup> human capital investment  $e$  enters in consumption and saving choices only via the

<sup>230</sup> intertemporal budget constraint:

$$c + \frac{c'}{1+r'} = (1+r)a + n(wzx(h)) + \frac{w'z'x(h')}{1+r'} \\ \text{with } h' = ze + (1-\delta)h.$$

<sup>231</sup> The log utility in consumption implies the optimality condition:

$$c' = \beta(1+r')c. \quad (13)$$

<sup>232</sup> Combining it with the budget constraint, we obtain the optimal consumption as a  
<sup>233</sup> function of labor supply  $n$  and human capital investment  $e$ :

$$c(n, e) = \frac{1}{1+\beta} \left[ (1+r)a + n(wzx(h)) + \frac{w'z'x(h' = ze + (1-\delta)h)}{1+r'} \right]. \quad (14)$$

### <sup>234</sup> 3.1.2 Labor supply and human capital investment

<sup>235</sup> The optimal consumption rules in (14) and (13) allow us to express the household's  
<sup>236</sup> problem as the maximization of an objective function in labor supply  $n$  and human  
<sup>237</sup> capital investment  $e$ :<sup>4</sup>

$$\max_{n,e} (1+\beta) \ln c(n, e) - \chi_n n - \chi_e e \quad (15)$$

<sup>238</sup> This maximization depends critically on the household's current human capital and  
<sup>239</sup> achievable next-period human capital. Accordingly, we partition households into  
<sup>240</sup> five ranges of  $h$ :  $[0, h_M]$ ,  $[h_M, h_M(1-\delta)^{-1}]$ ,  $[h_M(1-\delta)^{-1}, h_H]$ ,  $[h_H, h_H(1-\delta)^{-1}]$ ,  
<sup>241</sup> and  $[h_H(1-\delta)^{-1}, h_{\max}]$ .

<sup>242</sup> We now derive the decision rules for households  $h \in [h_M, h_M(1-\delta)^{-1}]$  in detail,  
<sup>243</sup> as the decision rules for the other four ranges are similar. For households with  
<sup>244</sup>  $h < h_M(1-\delta)^{-1}$ , we define two cutoffs in  $z$ :

$$\underline{z}_M(h) := \frac{h_M - (1-\delta)h}{e_H}; \bar{z}_M(h) := \frac{h_M - (1-\delta)h}{e_L} \quad (16)$$

<sup>245</sup> These cutoffs divide households into three groups based on their ability to be em-  
<sup>246</sup> ployed in the middle sector in the next period.

<sup>247</sup> **Non-learners** are households with  $z < \underline{z}_M(h)$ . They cannot achieve  $h' > h_M$   
<sup>248</sup> with either  $e_L$  or  $e_H$  level of human capital investment today. As a result, they will  
<sup>249</sup> choose not to invest in human capital,  $e = 0$ , and their future sectoral productivity

---

<sup>4</sup>This follows since  $c' = \beta(1+r')c$ , so  $\ln c' = \ln \beta + \ln(1+r') + \ln c$ .

250 will be  $x(h') = 1 - \lambda$ . These non-learners work  $n = 1$  if and only if  $z \geq \bar{z}_{non}^L(a)$ :

$$\bar{z}_{non}^L(a) = \frac{(\exp(\frac{\chi_n}{1+\beta}) - 1)[(1+r)a + \frac{w'z'(1-\lambda)}{1+r'}]}{w} \quad (17)$$

251 **Slow learners** are households with  $z \in (\underline{z}_M(h), \bar{z}_M(h))$ . These households can  
252 reach  $h' > h_M$  in the next period only by investing  $e = e_H$  today. Their choice  
253 is restricted to  $e = 0$  or  $e = e_H$ , since selecting  $e = e_L$  incurs a cost without any  
254 future benefit. Slow learners must trade off between working and human capital  
255 investment: choosing  $e = e_H$  requires not working today ( $n = 0$ ), while opting to  
256 work means forgoing investment in human capital ( $n = 1, e = 0$ ).<sup>5</sup>

257 Slow learners prefer  $(n = 1, e = 0)$  to  $(n = 0, e = e_H)$  if and only if  $z \geq \bar{z}_{slow}^L(a)$ :

$$\bar{z}_{slow}^L(a) = \frac{(\exp(\frac{\chi_n - \chi_e e_H}{1+\beta}) - 1)[(1+r)a + \frac{w'z'}{1+r'}] + \lambda \frac{w'z'}{1+r'}}{w} \quad (18)$$

258 **Fast learners** are households with  $z > \bar{z}_M(h)$ . They can achieve  $h' > h_M$  in  
259 the next period if they invest  $e = e_L$  today. In this case, there is no need to exert  
260 high effort  $e_H$  in human capital investment. The fast learners choose among three  
261 options:  $(n = 1, e = 0)$ ,  $(n = 1, e = e_L)$ , and  $(n = 0, e = e_L)$ .<sup>6</sup>

262 The decision rule for fast learners are as follows:

$$n(z, h, a), e(z, h, a) = \begin{cases} n = 1, e = 0 & \text{if } z \geq \bar{z}_{fast}^L(a) \\ n = 1, e = e_L & \text{if } \underline{z}_{fast}^L(a) \leq z < \bar{z}_{fast}^L(a) \\ n = 0, e = e_L & \text{if } z < \underline{z}_{fast}^L(a) \end{cases} \quad (19)$$

263 where

$$\bar{z}_{fast}^L(a) = \frac{\left\{ \exp(\frac{\chi_e e_L}{1+\beta}) \lambda \left[ \exp(\frac{\chi_e e_L}{1+\beta}) - 1 \right]^{-1} - 1 \right\} \frac{w'z'}{1+r'} - (1+r)a}{w} \quad (20)$$

264

$$\underline{z}_{fast}^L(a) = \frac{(\exp(\frac{\chi_n}{1+\beta}) - 1)[(1+r)a + \frac{w'z'}{1+r'}]}{w} \quad (21)$$

265 We set up our model so that  $\bar{z}_{fast}^L(a) > \underline{z}_{fast}^L(a)$ .<sup>7</sup>

---

<sup>5</sup>The choice between  $(n = 0, e = e_H)$  and  $(n = 0, e = 0)$  does not depend on  $z$ . For  $e_H$  to be relevant,  $\lambda$  must be large enough so that  $(n = 0, e = e_H)$  is preferred to  $(n = 0, e = 0)$ . See the Appendix for details on the lower bound for  $\lambda$ .

<sup>6</sup>Similar to the case of slow learners, the choice between  $(n = 0, e = e_L)$  and  $(n = 0, e = 0)$  does not depend on  $z$ . Moreover, since our model is set up so that  $(n = 0, e = e_H)$  dominates  $(n = 0, e = 0)$ , it implies that  $(n = 0, e = e_L)$  dominates  $(n = 0, e = 0)$ .

<sup>7</sup>Appendix A.2 provides the parameter restrictions such that the condition for  $(n = 0, e = e_H)$  to dominate  $(n = 0, e = 0)$  is sufficient for  $\bar{z}_{fast}^L(a) > \underline{z}_{fast}^L(a)$ .

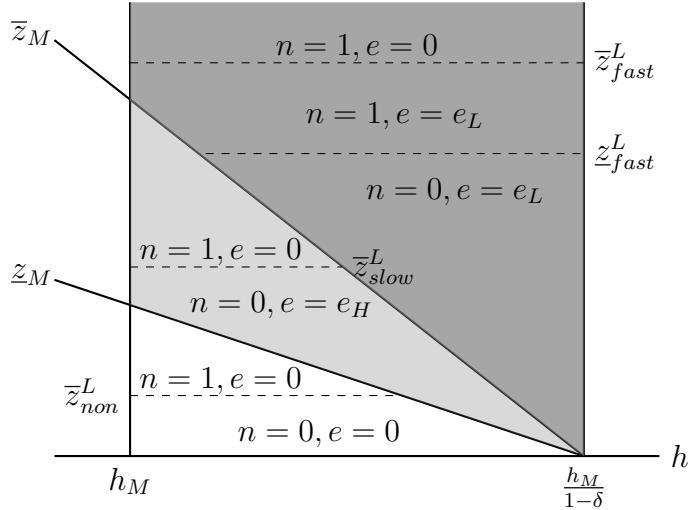

Figure 1: Decision Rule Diagram for  $h_M \leq h < h_M(1 - \delta)^{-1}$

The human capital  $h$  changes along the horizontal line and the idiosyncratic productivity  $z$  changes along the vertical line. The two diagonal lines,  $\bar{z}_M(h)$  and  $\underline{z}_M(h)$ , separate the state space into three areas: the unshaded area represents the non-learners, the lightly-shaded area represents the slow learners, and the darkly-shaded area represents the fast learners. The areas are divided by four dashed horizontal lines associated with cutoffs  $\bar{z}_{non}^L$ ,  $\bar{z}_{slow}^L$ ,  $\underline{z}_{fast}^L$ , and  $\bar{z}_{fast}^L$  that are functions of capital holding  $a$ .

**Decision rule diagram:** Figure 1 illustrates the decision rule  $(n, e)$  as a function of states  $(z, h, a)$  for households with  $h_M \leq h < h_M \frac{1}{1-\delta}$ . The human capital  $h$  changes along the horizontal line and the idiosyncratic productivity  $z$  changes along the vertical line. The two diagonal lines,  $\bar{z}_M(h)$  and  $\underline{z}_M(h)$  defined in (16), separate the state space into three areas: the unshaded area represents the non-learners, the lightly-shaded area represents the slow learners, and the darkly-shaded area represents the fast learners. The areas are divided by four dashed horizontal lines associated with cutoffs  $\bar{z}_{non}^L(a)$ ,  $\bar{z}_{slow}^L(a)$ ,  $\underline{z}_{fast}^L(a)$ , and  $\bar{z}_{fast}^L(a)$  that are functions of capital holding  $a$  and defined in (17), (18), (21), and (20).

This decision rule diagram is representative for households in other four ranges of human capital. Figure 2 illustrates the regions in which households make positive human capital investments. Striped shading highlights where investment occurs, with dark areas denoting fast learners and light areas representing slow learners.

For households with  $h < h_M$ ,  $\bar{z}_M(h)$  and  $\underline{z}_M(h)$  continue to be the boundaries that separate non-learners, slow learners and fast learners, but the four cutoffs are  $\bar{z}_{non}^L \frac{1}{1-\lambda}$ ,  $\bar{z}_{slow}^L \frac{1}{1-\lambda}$ ,  $\underline{z}_{fast}^L \frac{1}{1-\lambda}$ , and  $\bar{z}_{fast}^L \frac{1}{1-\lambda}$ .

For households with  $h_M \frac{1}{1-\delta} \leq h < h_H \frac{1}{1-\delta}$ , the boundaries for state space division change to  $\bar{z}_H(h)$  and  $\underline{z}_H(h)$ :

$$\underline{z}_H(h) := \frac{h_H - (1 - \delta)h}{e_H}; \quad \bar{z}_H(h) := \frac{h_H - (1 - \delta)h}{e_L} \quad (22)$$

If  $h_M \frac{1}{1-\delta} \leq h < h_H$ , the four cutoffs that partition the decision regions for households

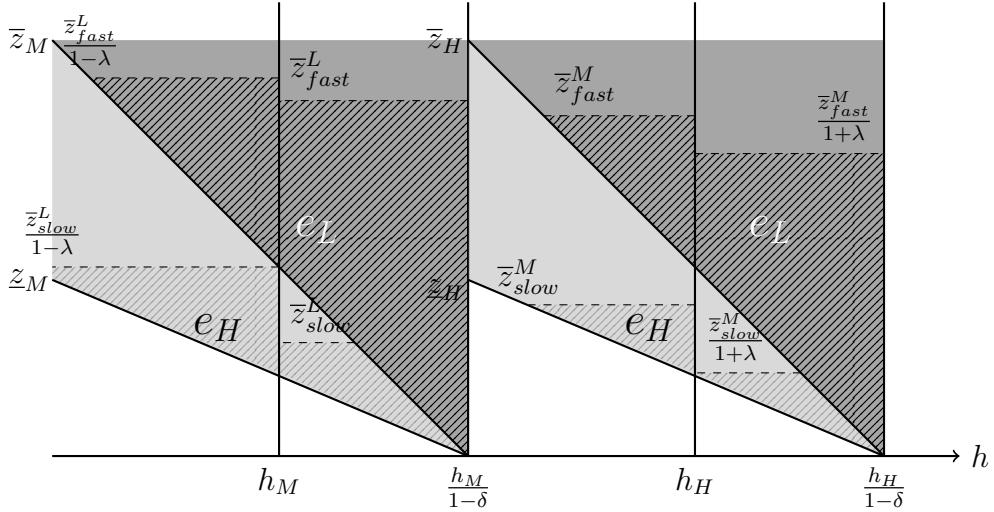

Figure 2: State Space for Human Capital Investment

The darkly-shaded striped areas indicate the state space for human capital investment equal to  $e_L$  by the fast learners. The lightly-shaded striped areas indicate the state space for human capital investment equal to  $e_H$  by the slow learners.

are denoted as  $\bar{z}_{non}^M(a)$ ,  $\bar{z}_{slow}^M(a)$ ,  $\underline{z}_{fast}^M(a)$ , and  $\bar{z}_{fast}^M(a)$  (see Appendix A.1 for the explicit formulae).<sup>8</sup> If  $h_H \leq h < h_H \frac{1}{1-\delta}$ , the analogous cutoffs are given by  $\bar{z}_{non}^M \frac{1}{1+\lambda}$ ,  $\bar{z}_{slow}^M \frac{1}{1+\lambda}$ ,  $\underline{z}_{fast}^M \frac{1}{1+\lambda}$ , and  $\bar{z}_{fast}^M \frac{1}{1+\lambda}$ .

Households with  $h \geq h_H \frac{1}{1-\delta}$  are always non-learners, since their human capital guarantees high-sector employment next period without further investment. For them, only the cutoff  $\bar{z}_{non}^H(a) \frac{1}{1+\lambda}$  matters.

### 3.2 The Effects of Uninsured Idiosyncratic Risk

We now reintroduce the idiosyncratic risk to households in period 1 by assuming that  $z'$  follows a log-normal distribution with mean  $\bar{z}'$  and variance  $\sigma_z^2$ .

Our previous analysis without uncertainty is a special case with  $\sigma_z^2 = 0$ . The effects of uninsured idiosyncratic risk can be thought as how households' decisions change when the distribution of  $z'$  undergoes a mean-preserving spread in the sense of second-order stochastic dominance.

From a consumption-saving perspective, the uncertain  $z'$  is associated with future labor income risk. It is well understood in the literature that idiosyncratic future income risk raises the expected marginal utility of future consumption for households with log utility and makes them save more. In our model, households can also supply more labor to mitigate the effect of idiosyncratic income risk on the marginal utility of consumption.

From the perspective of human capital investment, the uncertain  $z'$  is associated with risk in the return to human capital. Conditional on working, households'

<sup>8</sup>Appendix A.2 provides parameter restrictions for  $\bar{z}_{fast}^M(a) > \underline{z}_{fast}^M(a)$ .

306 income increases with  $z'$ :  $c' = (1 + r')a' + w'x(h')z'$ .  $\ln(c')$  is increasing and concave  
 307 in  $z'$ , and a higher  $x(h')$  increases the concavity.<sup>9</sup> Consider two levels of  $h'$ ,  $\bar{h}' > \underline{h}'$ , a  
 308 mean-preserving spread of  $z'$  distribution reduces the expected utility at both levels  
 309 of  $h'$  but the reduction is larger for the higher level  $\bar{h}'$ . Hence, the expected utility  
 310 gain of moving from  $\underline{h}'$  to  $\bar{h}'$  is smaller due to the idiosyncratic risk. Human capital  
 311 investment is discouraged.

312 Taking into account endogenous labor supply reinforces the discouragement of  
 313 human capital investment by the idiosyncratic risk. Recall from Section 3 that  
 314 households with  $z'$  lower than a cutoff do not work. The endogenous labor supply  
 315 therefore provides insurance against the lower tail risk of the idiosyncratic  $z'$ . More-  
 316 over, the cutoff in  $z'$  is lower for those with higher human capital  $h'$ . This makes  
 317 households with higher  $h'$  more exposed to the lower tail risk than those with lower  
 318  $h'$ , further reducing the gain of human capital investment.

319 **Proposition 1.** *The uninsured idiosyncratic risk in  $z'$  makes households in period  
 320 1 save more, work more and invest less in human capital.*

### 321 3.3 Period-1 Saving and Human Capital Investment

322 In this section, we study the impact of endogenous human capital investment on  
 323 households' saving decisions. Specifically, we compare optimal saving behavior in  
 324 two scenarios: one in which households can choose to invest in human capital, and  
 325 an alternative scenario in which human capital is exogenously fixed. To facilitate the  
 326 comparison, we assume in this section that there is no human capital depreciation.<sup>10</sup>

327 When the optimal choice of human capital investment is zero, optimal saving is  
 328 identical in both scenarios. When the optimal human capital investment is either  $e_L$   
 329 or  $e_H$ , we compare the household's optimal saving to the case where human capital  
 330 investment is exogenously fixed at zero, i.e.,  $(n = 1, e = 0)$ .<sup>11</sup>

---

<sup>9</sup>The marginal effect of  $z'$  on  $\ln(c')$  is

$$\frac{\partial \ln(c')}{\partial z'} = \frac{w'x(h')}{(1 + r')a' + w'x(h')z'} > 0$$

The second derivative is

$$\frac{\partial^2 \ln(c')}{(\partial z')^2} = - \left[ \frac{w'x(h')}{(1 + r')a' + w'x(h')z'} \right]^2 < 0$$

and is more negative if  $x(h')$  is higher.

<sup>10</sup>If depreciation is allowed, the analysis proceeds similarly but involves more comparison paris.

<sup>11</sup>Why not compare to  $(n = 0, e = 0)$ ? Such a comparison is not meaningful when considering  $(n = 1, e = e_L)$  because the two scenarios involve different state spaces. To see it, suppose conditions are such that  $(n = 1, e = e_L)$  is optimal. If we were to fix  $e = 0$  exogenously, the household's lifetime income would fall, and as a result the household would have a greater incentive to work. Thus, it is not possible for the household to deviate from choosing  $n = 1$  when human capital is held fixed at  $e = 0$ . The comparison between  $(n = 0, e = 0)$  and  $(n = 0, e = e_L \text{ or } e_H)$  is similar to the comparison between  $(n = 1, e = 0)$  to  $(n = 1, e = e_L)$ , since human capital investment does not affect period-1 labor income in either case.

<sup>331</sup> To make the human capital relevant, we assume that  $n' = 1$  in period 2. The  
<sup>332</sup> additive separability of work and human capital investment effort from consumption  
<sup>333</sup> allows us to consider the optimal saving conditional on a given choice of labor supply  
<sup>334</sup> and human capital investment.

<sup>335</sup> In particular, the household maximizes expected lifetime utility:

$$\max_{a'} : \ln(c) + \beta \mathbb{E}_{z'}[\ln(c')], \quad (23)$$

<sup>336</sup> subject to the budget constraints

$$c + a' = (1 + r)a + n(wzx(h)), \quad (24)$$

$$c' = (1 + r')a' + w'z'x(h'), \quad (25)$$

$$\text{with } h' = ze + (1 - \delta)h, e \in \{0, e_L, (1 - n)e_H\} \quad (26)$$

### <sup>337</sup> 3.3.1 Effect of on-job-training on saving

<sup>338</sup> We now compare the optimal saving between  $(n = 1, e = e_L)$  and  $(n = 1, e = 0)$ ,  
<sup>339</sup> where  $e_L$  allows households to move to a higher sector in period 2 with higher  
<sup>340</sup> sectoral productivity  $x(h')$ .

<sup>341</sup> To simplify the notation while maintaining the key economic forces, we normalize  
<sup>342</sup>  $(1 + r) = (1 + r') = 1$ ,  $w = w' = 1$ , the period-1 productivity shock  $z = 1$  and the  
<sup>343</sup> period-2 productivity shock  $z'$  to  $\ln z' \sim \mathcal{N}(0, \sigma_z^2)$ . The budget constraints become:

$$c + a' = a + x, \quad c' = a' + txz' \quad (27)$$

<sup>344</sup> where  $t \geq 1$  represents the effect of human capital investment on period-2 income:  
<sup>345</sup>  $t > 1$  if  $e = e_L$ ;  $t = 1$  if  $e = 0$ .

<sup>346</sup> The optimal saving is determined by the FOC:

$$\frac{1}{a + x - a'} = \beta \mathbb{E}_{z'}\left(\frac{1}{a' + txz'}\right) \quad (28)$$

<sup>347</sup> Denoting the mean and variance of  $z'$  as  $\mu$  and  $\Sigma$ , respectively:

$$\mu \equiv \mathbb{E}[z'] = e^{\sigma_z^2/2}, \quad \Sigma \equiv \text{Var}(z') = e^{\sigma_z^2}(e^{\sigma_z^2} - 1). \quad (29)$$

<sup>348</sup> The second-order approximate solution to the FOC is:

$$a'^*(x, a; t) = \underbrace{\frac{\beta(a + x) - tx\mu}{1 + \beta}}_{\text{CE}} + \underbrace{\frac{t^2 x^2 \Sigma}{\beta(a + x + tx\mu)}}_{\text{Precautionary}} \quad (30)$$

<sup>349</sup> The first term is the *certainty-equivalent* saving, which reflects the consumption  
<sup>350</sup> smoothing motive, increasing in the period-1 resources  $a + x$  and decreasing in the

351 period-2 expected labor income  $tx\mu$ . The second term is the *precautionary* saving,  
 352 which is increasing in the variance of period-2 labor income  $t^2x^2\Sigma$  and decreasing in  
 353 the expected total resources  $a + x + tx\mu$ .

354 The effect of on-job-training on saving can be decomposed into two components:

$$\frac{\partial a'^*}{\partial t}(x, a; t) = -\frac{x\mu}{1+\beta} + \frac{x^2\Sigma}{\beta} \frac{t[2(a+x) + tx\mu]}{(a+x+tx\mu)^2}. \quad (31)$$

355 The first term being negative captures the *crowd-out* effect on saving via consumption-  
 356 smoothing motive as on-job-training increases the expected period-2 labor income  
 357  $tx\mu$ . The second positive term captures the *crowd-in* effect via precautionary saving  
 358 motive as on-job-training exposes households to larger future income risk.

359 To capture the overall impact of on-job-training on saving, we define:

$$\Delta_{\text{on-job}}(x, a; t) = a'^*(x, a; t) - a'^*(x, a; 1) = \int_1^t \frac{\partial a'^*}{\partial u}(x, a; u) du, \quad (32)$$

360 where  $a'^*(x, a; t)$  is the optimal saving when households undertake on-job-training,  
 361 and  $a'^*(x, a; 1)$  is the optimal saving when human capital is kept exogenously fixed.

362 Whether on-job-training increases or decreases saving ultimately depends on  
 363 the balance between the crowd-out effect (via higher expected future income) and  
 364 the precautionary crowd-in effect (via heightened future income risk). The next  
 365 proposition demonstrates that these effects can dominate differently depending on  
 366 skill, so that the overall impact of on-job-training on saving can differ between low-  
 367 and high-skilled households.

368 **Proposition 2.** *When the idiosyncratic shock is large enough, i.e.,  $\frac{\Sigma}{\mu} > \underline{\sigma}(t)$ , on-*  
 369 *job-training crowds out saving for low-skilled households and crowds in saving for*  
 370 *high-skilled households: for  $x < x^*(a, t)$ ,  $e = e_L$  lowers saving  $\Delta_{\text{on-job}}(x, a; t) < 0$ ;*  
 371 *for  $x > x^*(a, t)$ ,  $e = e_L$  raises saving  $\Delta_{\text{on-job}}(x, a; t) > 0$ .*

372 *Proof.* See Appendix B. □

### 373 3.3.2 Effect of full-time training on saving

374 We next compare the optimal saving between  $(n = 0, e = e_L \text{ or } e_H)$  and  $(n =$   
 375  $1, e = 0)$ . Note that full-time training requires the households to give up their labor  
 376 income in period 1, which is not the case for on-job-training. Following the same  
 377 normalization and notation as in the previous subsection, we can write the budget  
 378 constraints with full-time training and without training as:

$$e = e_H : c + a' = a, \quad c' = a' + txz' \quad (33)$$

$$e = 0 : c + a' = a + x, \quad c' = a' + xz' \quad (34)$$

379 where  $t > 1$  captures the effect of full-time training on period-2 income.

380 The second-order approximate solution to the optimization problem is:

$$e = e_H : \quad a'_{e_H}^*(x, a; t) = \underbrace{\frac{\beta a - tx\mu}{1 + \beta}}_{\text{CE}} + \underbrace{\frac{t^2 x^2 \Sigma}{\beta(a + tx\mu)}}_{\text{Precautionary}} \quad (35)$$

$$e = 0 : \quad a'^*(x, a; 1) = \underbrace{\frac{\beta(a + x) - x\mu}{1 + \beta}}_{\text{CE}} + \underbrace{\frac{x^2 \Sigma}{\beta(a + x + x\mu)}}_{\text{Precautionary}} \quad (36)$$

381 so that the total effect of full-time training on saving is:

$$\Delta_{\text{full-time}}(x, a; t) = a'_{e_H}^*(x, a; t) - a'^*(x, a; 1) \quad (37)$$

$$= \Delta_{\text{on-job}}(x, a; t) - x \frac{\beta}{1 + \beta} + \frac{t^2 x^2 \Sigma}{\beta} \frac{x}{(a + x + tx\mu)(a + tx\mu)} \quad (38)$$

382 Compared to the effect of on-job-training, represented by  $\Delta_{\text{on-job}}(x, a; t)$  defined in  
 383 (32), full-time training introduces two additional effects on saving. First, it further  
 384 reduces saving because households forgo their period-1 labor income, as reflected  
 385 in the second term. Second, it increases precautionary saving, since having lower  
 386 current resources leaves households less able to self-insure against idiosyncratic risk  
 387 in period 2, which is captured by the third term. Denote the net additional effect  
 388 of full-time training on saving as:

$$\Delta_H(x, a; t) \equiv x \left[ -\frac{\beta}{1 + \beta} + \frac{\Sigma}{\beta} \frac{t^2 x^2}{(a + x + tx\mu)(a + tx\mu)} \right] \quad (39)$$

389 so that  $\Delta_{\text{full-time}}(x, a; t) = \Delta_{\text{on-job}}(x, a; t) + \Delta_H(x, a; t)$ . The next proposition shows  
 390 that the net additional effect is negative and stronger for higher skilled households.

391 **Proposition 3.** *When the idiosyncratic shock is not too large, i.e.,  $\frac{\Sigma}{\mu} < \bar{\sigma}(t)$ , full-  
 392 time training crowds out more saving than on-job-training,  $\Delta_H(x, a; t) < 0$ . More-  
 393 over, the crowding-out effect is stronger for higher skilled households:  $\Delta_H(x, a; t)$  is  
 394 decreasing in  $x$ .*

395 *Proof.* See Appendix B. □

### 396 3.4 The Effects of an Anticipated Period-2 AI Shock

397 Suppose that an AI shock is anticipated to occur in period 2 and to increase the

398 labor productivity for the low sector and the high sector but not the middle sector.

399 The effect of AI shock on the sectoral productivity is captured by  $\gamma$  with  $0 < \gamma < 1$ :

$$x(h') = \begin{cases} 1 - \lambda + \gamma\lambda & \text{low sector if } h' < h_M \\ 1 & \text{middle sector if } h_M < h' < h_H \\ 1 + \lambda + \gamma\lambda & \text{high sector if } h' > h_H \end{cases} \quad (40)$$

<sup>400</sup> In other words, the AI shock increases average labor productivity, reduces the earnings  
<sup>401</sup> premium for the middle sector, and enlarges the earnings premium for the high  
<sup>402</sup> sector relative to the middle sector.

### <sup>403</sup> 3.4.1 Effects on human capital investment

<sup>404</sup> The AI shock lowers the incentive to work in the middle sector in period 2. Consequently,  
<sup>405</sup> households with  $h < h_M/(1 - \delta)$  reduce their human capital investment,  
<sup>406</sup> while those with  $h > h_M/(1 - \delta)$  increase it. More specifically, the upper bounds  
<sup>407</sup> that determine whether households undertake positive human capital investment –  
<sup>408</sup> denoted by  $\bar{z}_{slow}^L$  and  $\bar{z}_{fast}^L$  for  $h < h_M/(1 - \delta)$ , and  $\bar{z}_{slow}^M$  and  $\bar{z}_{fast}^M$  for  $h > h_M/(1 - \delta)$   
<sup>409</sup> – respond in opposite directions to the anticipated shock: the former decrease with  
<sup>410</sup>  $\gamma$  and the latter increase. This relationship is formalized below.

<sup>411</sup> **Proposition 4.** *An anticipated AI shock decreases human capital investment among  
<sup>412</sup> households with  $h < h_M/(1 - \delta)$ , but increases it among those with  $h > h_M/(1 - \delta)$ .  
<sup>413</sup> Specifically,  $\bar{z}_{slow}^L$  and  $\bar{z}_{fast}^L$  decrease with  $\gamma$ , while  $\bar{z}_{slow}^M$  and  $\bar{z}_{fast}^M$  increase with  $\gamma$ .*

<sup>414</sup> *Proof.* See Appendix B. □

### <sup>415</sup> 3.4.2 Effects on labor supply

<sup>416</sup> **via income:** The AI shock raises period-2 labor income for households who will  
<sup>417</sup> work in the low or high sector, leading to a positive income effect that reduces their  
<sup>418</sup> labor supply in period 1.

<sup>419</sup> **via full-time training:** Because full-time training and labor supply compete for  
<sup>420</sup> time, the AI shock affects their tradeoff through its impact on human capital invest-  
<sup>421</sup> ment incentives. For  $h > h_M/(1 - \delta)$ , where AI makes investing in additional skills  
<sup>422</sup> more attractive, households are more likely to engage in full-time training and thus  
<sup>423</sup> reduce period-1 labor supply. In contrast, for  $h < h_M/(1 - \delta)$ , where the AI shock  
<sup>424</sup> lowers the payoff to investing in skills, households shift away from full-time training  
<sup>425</sup> and supply more labor in the first period.

### <sup>426</sup> 3.4.3 Effects on saving

<sup>427</sup> The AI shock increases sectoral labor productivities for the low and high sectors in  
<sup>428</sup> period 2, while leaving the middle sector's labor productivity unchanged. Its effect  
<sup>429</sup> on saving can be analyzed as if we are varying the parameter  $t$  in the functions  
<sup>430</sup>  $\Delta_{on-job}(x, a; t)$ , defined in (32), and  $\Delta_H(x, a; t)$ , defined in (39).

<sup>431</sup> **Proposition 5.**  $\Delta_{on-job}(x, a; t)$  is convex in  $t$ .  $\Delta_H(x, a; t)$  is increasing in  $t$ .

<sup>432</sup> • If  $\Delta_{on-job}(x, a; t) > 0$  and  $t > 1$ ,  $\Delta_{on-job}(x, a; t') > \Delta_{on-job}(x, a; t)$  for  $t' > t > 1$ .

- 433        • If  $\Delta_{on\text{-}job}(x, a; t) > 0$  and  $t < 1$ ,  $\Delta_{on\text{-}job}(x, a; t') < \Delta_{on\text{-}job}(x, a; t)$  for  $1 > t' > t$ .

434        *Proof.* See Appendix B. □

435        **Households who stay in the same sector** For middle-sector households, the  
436        AI shock leaves both their incomes and saving unchanged.

437        By contrast, low-sector and high-sector households experience an increase in  
438        period-2 labor income  $x'$  as a result of the AI shock. If they remain in the same  
439        sector without needing additional human capital investment or on-the-job training,  
440        their saving behavior in the absence of the AI shock can be compared to the scenario  
441        with fixed human capital. Following the AI shock, however, their situation resembles  
442        one with on-the-job training that enhances  $x'$  (i.e.,  $t > 1$ ). Thus, the effect of the  
443        AI shock on saving is captured by the on-the-job training impact,  $\Delta_{on\text{-}job}(x, a; t)$ .

444        As shown in Proposition 2,  $\Delta_{on\text{-}job}(x, a; t)$  has opposite signs for low-skill and  
445        high-skill households. This implies that the AI shock *crowds out* saving among  
446        low-sector households, while it *crowds in* saving for high-sector households.

447        For households who must undertake full-time training to remain in the high  
448        sector,  $\Delta_H(x, a; t)$  captures the additional effect of such training on saving. In this  
449        case, a higher  $x'$ —brought about by the AI shock—corresponds to an increase in  $t$ ,  
450        further boosting  $\Delta_H(x, a; t)$  (Proposition 5). Consequently, the AI shock *crowds in*  
451        saving for high-sector households in this scenario as well.

452        **Households who upskill** For low-sector households, saving behavior remains  
453        unchanged, as the AI shock does not affect their future productivity after upskilling.

454        For the middle-sector households who upskill via on-job-training, the AI shock  
455        boosts their future productivity gain from  $\lambda$  to  $(1 + \gamma)\lambda$ , which corresponds to a  
456        higher  $t$  in  $\Delta_{on\text{-}job}(x, a; t)$  with  $t > 1$ . According to Proposition 5, if the pre-shock  
457        effect of on-the-job training on saving is positive, the AI shock will *raise* saving.  
458        However, if this effect is negative, the overall impact of the AI shock on saving  
459        becomes ambiguous.

460        For the middle-sector households who upskill via full-time training, there is an  
461        *additional positive effect* of the AI shock on their saving, because a higher  $x'$  increases  
462         $\Delta_H(x, a; t)$  (Proposition 5).

463        **Households who downskill** Downsampling, which reflects human capital depre-  
464        ciation, does not require any new investment in skills. For high-sector households  
465        who transition downward, the AI shock leaves their future productivity – and thus  
466        their saving – unchanged.

467        For middle-sector households who downskill to the low sector, their saving differs  
468        from the fixed human capital scenario by  $\Delta_{on\text{-}job}(x, a; t)$  with  $t < 1$ . The AI shock  
469        mitigates their future productivity loss by reducing it from  $\lambda$  to  $(1 - \gamma)\lambda$ , effectively

470 increasing  $t$  to a new value  $t' < 1$ . According to Proposition 5, if the pre-shock effect  
471  $\Delta_{\text{on-job}}(x, a; t)$  is positive, the AI shock will *reduce* saving. If this effect is negative,  
472 however, the overall impact of the AI shock on saving is ambiguous.

### 473 3.5 *Limitations of the two-period model*

474 Up to this point, our analysis has focused on how AI influences household-level  
475 decisions regarding human capital investment, labor supply, and saving within the  
476 framework of a two-period model. While this provides valuable insights into indi-  
477 vidual behavioral responses, understanding the broader, economy-wide implications  
478 of AI requires moving to a more comprehensive setting – a quantitative model with  
479 an infinite time horizon, endogenous asset accumulation, and general equilibrium  
480 feedback.

481 **General equilibrium (GE) effects** When households adjust their investment in  
482 human capital, labor supply, and savings in response to AI, these changes aggregate  
483 up to affect the total supply of effective labor and capital in the economy. As these  
484 aggregates shift, they exert downward or upward pressure on the wage rate and  
485 the interest rate, feeding back into each household’s optimization problem. Thus,  
486 general equilibrium effects capture the intricate loop by which individual decisions  
487 shape, and are shaped by, the macroeconomic environment.

488 **Composition effects** Endogenizing human capital investment injects dynamism  
489 into how households sort themselves among the three skill sectors. When an AI shock  
490 occurs, individuals may choose to retrain, upskill, or even move to lower-skilled work,  
491 reshaping the distribution of labor across sectors. This shifting composition changes  
492 the relative size of each sector, with significant consequences for both aggregate  
493 outcomes and the distributional effects of AI.

## 494 4 A Quantitative Model

495 We now solve the full dynamic model with infinite horizon, endogenous asset accu-  
496 mulation, and general equilibrium. We calibrate the model to reflect key features of  
497 the U.S. economy, capturing reasonable household heterogeneity.

### 498 4.1 *Calibration*

499 We calibrate the model to match the U.S. economy. For several preference pa-  
500 rameters, we adopt values commonly used in the literature. Other parameters are  
501 calibrated to align with targeted moments. The model operates on an annual time  
502 period. Table I summarizes the parameter values used in the benchmark model.

Table I: Parameters for the Calibration

Parameter	Value	Description	Target or Reference
$\beta$	0.91795	Time discount factor	Annual interest rate
$\rho_z$	0.94	Persistence of $z$ shocks	See text
$\sigma_z$	0.287	Standard deviation of $z$ shocks	Earnings Gini
$\underline{a}$	0	Borrowing limit	See text
$\chi_n$	2.47	Disutility from working	Employment rate
$\chi_e$	1.48	Disutility from HC effort	See text
$\bar{n}$	1/3	Hours worked	Average hours worked
$e_H$	1/3	High level of effort	Average hours worked
$e_L$	1/6	Low level of effort	See text
$h_M$	0.41	Human capital cutoff for M	See text
$h_H$	0.96	Human capital cutoff for H	See text
$\lambda$	0.2	Skill premium	Income Gini
$\alpha$	0.36	Capital income share	Standard value
$\delta$	0.1	Capital depreciation rate	Standard value

503        The time discount factor,  $\beta$ , is calibrated to match an annual interest rate of 4  
 504        percent. We set  $\chi_n$  to replicate an 80 percent employment rate. We calibrate  $\chi_e$  to  
 505        match the fact that around 30 percent of the population invests in human capital.  
 506        The borrowing limit,  $\underline{a}$ , is set to 0.

507        We calibrate parameters regarding labor productivity process as follows. We  
 508        assume that  $x$  follows the AR(1) process in logs:  $\log z' = \rho_z \log z + \epsilon_z$ , where  
 509         $\epsilon_z \sim N(0, \sigma_z^2)$ . The shock process is discretized using the Tauchen (1986) method,  
 510        resulting in a transition probability matrix with 9 grids. The persistence parameter  
 511         $\rho_z = 0.94$  is chosen based on estimates from the literature. The standard deviation  
 512         $\sigma_z$ , is chosen to match the earnings Gini coefficient of 0.63.

513        We deviate from the two-period model by assuming that the labor supply is a  
 514        discrete choice between 0 and  $\bar{n} = 1/3$ . This change only rescales the two-period  
 515        model without altering the trade-off facing the households. But such rescaling facil-  
 516        itates the interpretation that households are deciding whether to allocate one-third  
 517        of their fixed time endowment to work. The high-level human capital accumulation  
 518        effort,  $e_H$  is assumed to equal  $\bar{n}$ . The low-level effort,  $e_L$  is set to half of  $e_H$ . The skill  
 519        premium across sectors,  $\lambda$ , is set at 0.2 to match the income Gini coefficient. Human  
 520        capital cutoffs,  $h_M$  and  $h_H$ , are set so that the population shares in low, middle, and  
 521        high sectors are, respectively, 20, 40, and 40 percent. This population distribution  
 522        roughly matches the fractions of U.S. workers in 2014 who are employed in routine  
 523        manual occupations (low sector), routine cognitive and non-routine manual (middle  
 524        sector), and non-routine cognitive (high sector) (Cortes *et al.*, 2017).

525        On the production side, we set the capital income share,  $\alpha$ , to 0.36, and the  
 526        depreciation rate,  $\delta$ , to 0.1.

Table II: Key Moments

Moment	Data	Model
Employment rate	0.80	0.80
Human capital investment ratio	0.29	0.29
Gini coefficient for wealth	0.78	0.76
Gini coefficient for earnings	0.63	0.62
Gini coefficient for income	0.57	0.58

## 527 4.2 Key Moments: Data vs. Model

528 In Table II, we present a comparison of key moments between the model and the  
 529 empirical data. The model does an excellent job of replicating the 80% employment  
 530 rate observed in the data. In this context, employment is defined as having positive  
 531 labor income in the given year, consistent with the common approach used in the  
 532 literature. According to OECD (1998), the share of the population investing in  
 533 human capital—those who are actively engaged in skill acquisition or education—is  
 534 approximately 30%, a figure well matched by the model’s predictions. This is an  
 535 important metric because it reflects the model’s capacity to capture the dynamics  
 536 of human capital formation, which plays a critical role in shaping long-run earnings  
 537 and income inequality. Additionally, the model accurately captures the distribution  
 538 of income and earnings, aligning closely with observed data. This suggests that the  
 539 model effectively incorporates the key mechanisms driving labor market outcomes  
 540 and the corresponding distributional aspects of earnings. Although the model does  
 541 not explicitly target the wealth Gini coefficient, it achieves a close match to the  
 542 data: the empirical wealth Gini is 0.78, while the model produces a value of 0.76.  
 543 This highlights the model’s ability to capture substantial wealth inequality in the  
 544 economy.

## 545 4.3 Steady-state Distribution

546 Table III presents the steady-state distribution of population, employment, and  
 547 assets across sectors. The population shares are calibrated to 20%, 40%, and  
 548 40% by adjusting the human capital thresholds that define sectors. The shares  
 549 of employment and assets are endogenously determined by households’ labor supply  
 550 and savings decisions. Notably, the high sector accounts for 46% of total employ-  
 551 ment—exceeding its population share—indicating that a disproportionate number  
 552 of households choose to work in that sector. Asset holdings are even more skewed:  
 553 the high sector holds 68% of total assets, while the low sector holds only 8%.

Table III: Distribution of Population, Employment and Assets

Sectors	Pop. Share (%)	Emp. Share (%)	Assets Share (%)
Low	20.76	18.58	8.07
Middle	38.87	35.35	23.92
High	40.35	46.07	68.01

Note: Human capital cutoffs,  $h_H$  and  $h_M$ , determine the population share across sectors. Employment share and assets share are implied by households labor supply decisions and saving decisions.

Figure 3: Steady-state Human Capital Distribution

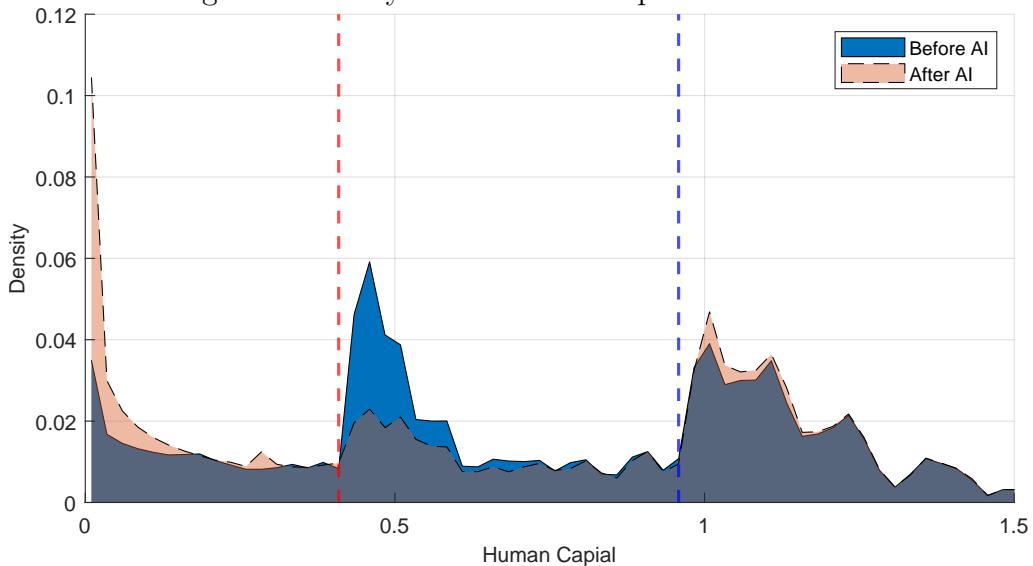

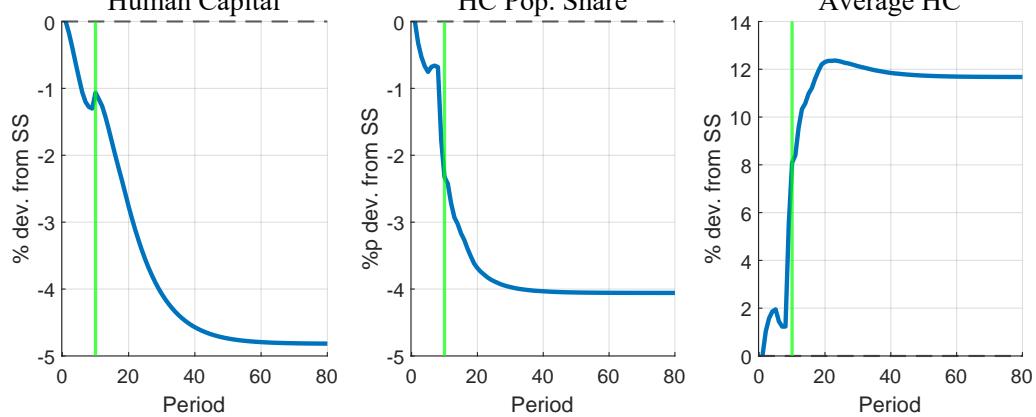

Figure 4: Transition Path for Human Capital Investment

## 554 5 AI's Impact on Human Capital Adjustments

555 We now introduce AI technology into the quantitative model, assuming that it will  
556 be implemented in 10 years and that households have full information about its  
557 arrival. We examine both the transition dynamics and the differences between the  
558 initial and new steady states. This framework allows us to analyze how the economy  
559 adjusts in anticipation of, and in response to, the adoption of AI.

560 The effect of AI on the sectorial productivity is modeled as in (40) with  $\gamma = 0.3$ .  
561 That is, AI boosted the productivity of the low sector workers by 7.5% and the  
562 productivity of the high sector workers by 5%, leaving the middle sector intact.  
563 It captures the key idea that AI increases average labor productivity (Acemoglu  
564 and Restrepo, 2019), but reduces the earning premium for the middle sector, and  
565 enlarges the earning premium for the higher sector relative the middle sector.

### 566 5.1 Human Capital Adjustments

567 Given the employment distribution in the initial steady state, AI is projected to  
568 increase the economy's labor productivity by 4% on average, assuming households  
569 do not alter their decisions in response. However, changes in earning premiums  
570 incentivize households to adjust their human capital investments.

571 **Steady-state human capital distribution:** Figure 3 illustrates how households  
572 reallocate across sectors in the new steady state relative to the initial one. The x-axis  
573 denotes the level of human capital, while the y-axis indicates the mass of households  
574 at each human capital level. The red vertical line marks the cutoff between the low  
575 and middle sectors, and the blue vertical line marks the cutoff between the middle  
576 and high sectors.

577 The gray shaded area shows the overlap between the two steady-state distri-  
578 butions. Within each sector, the distribution of households is skewed to the left,  
579 reflecting the tendency for human capital investment to be concentrated among  
580 those near the sectoral cutoffs. As shown in the decision rule diagram in Figure 2,  
581 some households seek to upgrade their skills, while others aim to remain in more  
582 skilled sectors. The blue shaded area highlights the mass of households who have  
583 exited the middle sector following the AI shock. The pink areas represent the addi-  
584 tional mass of households in the new steady-state distribution, concentrated at the  
585 lower end of the low sector and the lower end of the high sector.

586 **Transition path** Figure 4 reports the transition dynamics of aggregate human  
587 capital from the initial to the new steady state. The figure also displays its extensive  
588 margin (the share of households making positive human capital investments) and  
589 intensive margin (average human capital per household among those who invest).

590 As households reallocate from the middle sector to the low and high sectors, the  
591 net effect is a gradual decline in aggregate human capital along the transition path.  
592 This mirrors the steady-state change observed in Figure 3, where the increased mass  
593 at the lower end of the low sector outweighs the increase in the high sector.

594 Additionally, human capital accumulation becomes increasingly concentrated  
595 among a smaller share of the population. The proportion of households making  
596 positive human capital investments steadily declines, ultimately stabilizing at a level  
597 4% lower than in the initial steady state. Meanwhile, the average human capital  
598 among those who invest rises, reaching a level 12% higher than the initial steady  
599 state in the long run.<sup>12</sup>

## 600 5.2 Job Polarization

601 An important implication of human capital adjustments to the AI shock is job  
602 polarization. Figure 5 illustrate the transition paths of population shares and em-  
603 ployment rates in each sector. Notably, the middle sector experiences a significant  
604 decline, with its population share decreasing by approximately 13%. Additionally,  
605 employment within this sector plummets to a level 16% lower than the initial steady  
606 state. In contrast, both the low and high sectors see increases in their population  
607 shares and employment rates. These dynamics indicate a reallocation of *workers*  
608 from the middle sector to the low and high sectors following the introduction of AI.

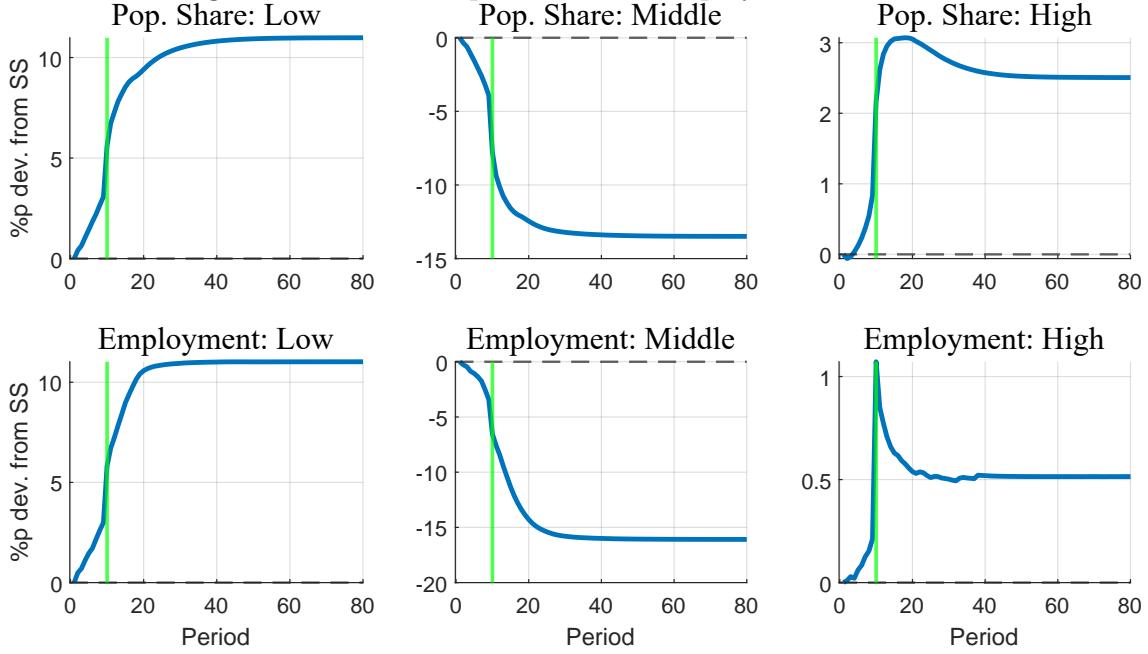

609 **Voluntary job polarization** This worker reallocation aligns with the phenomenon  
610 of “job polarization”(Goos *et al.*, 2014), where AI and automation technologies dis-  
611 proportionately replace tasks commonly performed by middle-skilled workers. How-  
612 ever, our model introduces a complementary mechanism to the conventional under-  
613 standing of this reallocation. Specifically, households in our model voluntarily exit  
614 the middle sector even before AI implementation by adjusting their human capital  
615 investments – many middle-sector workers opt for non-employment to invest in skills  
616 that will better position them for the post-AI labor market. To emphasize this key  
617 difference, our model deliberately abstracts from any direct negative effect of AI on  
618 middle-sector workers.

619 **Employment flows more towards the low sector** Another intriguing finding  
620 in our model is the more pronounced employment effect in the low sector compared  
621 to the high sector. In the new steady state, the employment rate in the low sector  
622 increases by 12%, whereas in the high sector, it rises by only 0.5%. This asymmetry  
623 in employment rate changes suggests an unbalanced reallocation of workers from the  
624 middle sector, with a greater flow toward the low sector.

---

<sup>12</sup>The only exception to those patterns occurs at period 10 when the positive effects of AI on sectoral productivity are realized.

Figure 5: Sectoral Population and Employment Transition

Note: The transition paths within each sector. The x-axis represents years, and the y-axis shows the percentage (or percentage point) deviation from the initial steady state. AI introduction is assumed to occur in period 10. “Pop. Share” denotes the population share within each sector. “Employment” is the percentage of households who are employed in each sector.

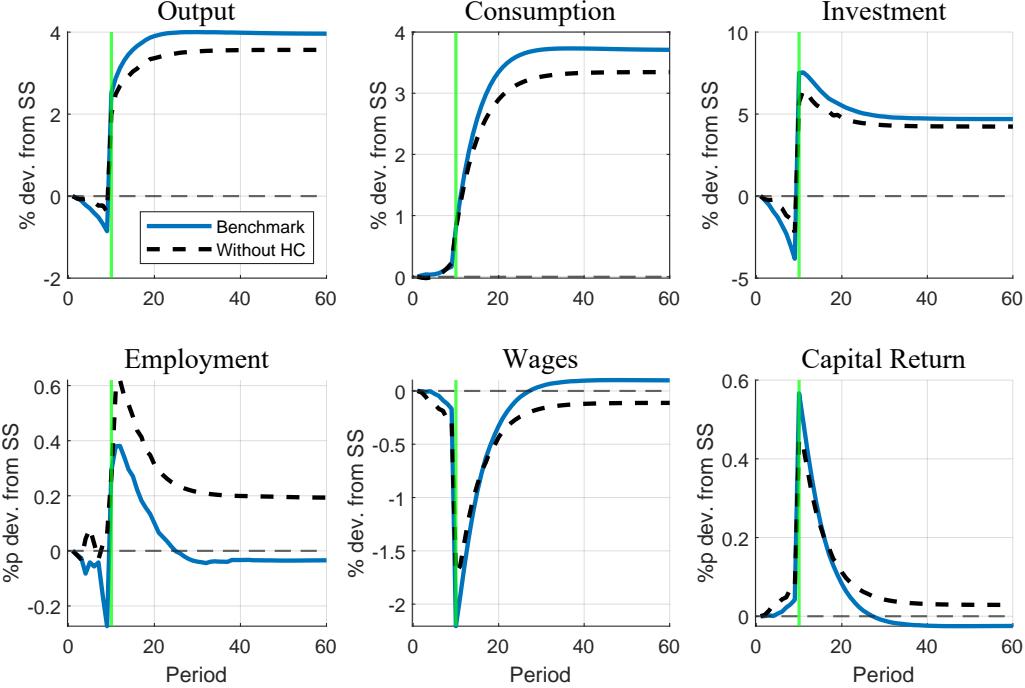

625 This disparity arises from two key factors. First, AI enhances the productivity of  
 626 low-sector workers by 7.5% and high-sector workers by 5%. However, this produc-  
 627 tivity differential alone does not fully account for the significant asymmetry. The  
 628 second factor is the variation in labor supply elasticity across sectors. Compared to  
 629 the high sector, the low sector exhibits higher labor supply elasticity, meaning that  
 630 the same change in labor earnings triggers larger labor supply responses. This is  
 631 because households in the low sector have lower consumption levels, making their  
 632 marginal utility of consumption more sensitive to changes in their budget. Con-  
 633 sequently, a greater proportion of households in the low sector are at the margin  
 634 between employment and non-employment (Chang and Kim, 2006).

## 635 6 The Aggregate and Distributional Effects of AI

636 The aggregate and distributional effects of AI are shaped by both its direct impact on  
 637 sectoral productivity and the endogenous response of human capital accumulation.  
 638 By altering sectoral productivity, AI changes labor earnings, which in turn influences  
 639 labor supply decisions and savings through income effects. Consequently, AI directly  
 640 affects the supply of labor and capital, generating aggregate economic responses.  
 641 Because AI’s productivity effects are heterogeneous across sectors, its impact is  
 642 inherently distributional.

643 These sectoral differences also induce human capital adjustments, as households  
 644 reallocate across sectors in response to changing incentives. This reallocation not

Figure 6: Transition Path of Aggregate Variables: Benchmark vs. No HC Models.

Note: The transition paths of aggregate variables: benchmark vs. No HC models. The x-axis represents years, and the y-axis shows the percentage deviation from the initial steady state. AI introduction is assumed to occur in period 10. The No HC model is an economy in which workers maintain their initial steady-state level of human capital throughout the AI implementation until the new steady state is reached.

only shifts the distribution of labor productivity and aggregate productivity, but also directly shapes distributional outcomes, as households' relative positions in the income and asset distributions are altered by their movement across sectors.

In this section, we examine the importance of endogenous human capital adjustment in shaping both the transitional and long-run effects of AI. To do so, we compare the benchmark economy – where households endogenously adjust their human capital – with an alternative scenario in which households are held fixed at their initial steady-state human capital during the AI transition (“No HC model”). In both cases, households make endogenous decisions about consumption, savings, and labor supply.

By contrasting the transition dynamics across these two economies, we can disentangle the direct and indirect effects of AI. The transition path in the No-HC-model isolates the direct impact of AI on aggregate and distributional outcomes, as it abstracts from any human capital adjustments. The difference in outcomes between the benchmark and the No-HC-model then reveals the indirect effects of AI that operate through households' adjustments in human capital. This decomposition allows us to assess the relative importance of human capital dynamics in driving both the aggregate and distributional consequences of AI.

663 *6.1 Aggregate Implications*

664 Figure 6 shows the transition paths of key macroeconomic variables—output, con-  
665 sumption, investment, and employment—as well as factor prices, including the wage  
666 rate and capital return. The blue solid lines depict results from the benchmark model  
667 with endogenous human capital adjustment, while the black dashed lines represent  
668 the No-HC model in which human capital is held fixed.

669 **6.1.1 AI's direct impacts**

670 The No-HC-model isolates the direct effects of AI. In the long run, the introduction  
671 of AI leads to higher output, consumption, investment, and employment. However,  
672 in anticipation of AI (prior to period 10), output and investment decline, while  
673 consumption and employment remain stable.

674 Before the implementation of AI, sectoral productivity is unchanged; the only  
675 difference is households' awareness of future increases in productivity in the low and  
676 high sectors beginning in period 10. This anticipation raises households' expected  
677 lifetime income, prompting them to save less and consume more ahead of the actual  
678 productivity gains. As a result, aggregate capital stock falls, which lowers output and  
679 reduces the marginal product of labor while raising the marginal product of capital.  
680 Employment remains largely unchanged in this period, as sectoral productivity has  
681 not yet shifted.

682 Following the AI shock, sectoral productivity in the low and high sectors rises,  
683 boosting labor income, employment, and output in these sectors. Because produc-  
684 tivity gains are labor-augmenting, the supply of efficient labor units rises sharply,  
685 causing wages to decline and capital returns to increase. Employment and invest-  
686 ment both adjust to dampen these factor price changes. In the new steady state, the  
687 wage rate is slightly below its initial level, while the return to capital is marginally  
688 higher.

689 **6.1.2 AI's indirect impacts via endogenous human capital adjustments**

690 The difference between the No-HC model and the benchmark model captures the  
691 indirect effects of AI operating through endogenous human capital adjustments.  
692 Among all macroeconomic variables, this indirect effect is most pronounced for em-  
693 ployment.

694 In anticipation of AI, employment declines as some households temporarily exit  
695 the labor market to invest in human capital and prepare for the post-AI economy.<sup>13</sup>  
696 During this period, labor productivity remains unchanged, so the decline in em-  
697 ployment directly translates to a reduction in output. Consistent with standard

---

<sup>13</sup>Empirical studies, such as Lerch (2021) and Faber *et al.*, (2022), support the short-term adverse effects of AI adoption on labor markets.

698 consumption-smoothing behavior, this reduction is mainly absorbed by lower  
699 investment. Meanwhile, the drop in employment mitigates the direct effects of AI on  
700 both wages and capital returns prior to the AI implementation.

701 After AI is introduced, employment rebounds as sectoral productivity increases.  
702 However, continued human capital investment by middle-sector households keeps  
703 employment lower than in the No-HC model, resulting in an almost neutral long-  
704 run effect of AI on employment. Despite this, output, consumption, and investment  
705 are all higher in the benchmark model because human capital adjustments reallocate  
706 more labor to the low and high sectors, thereby better capturing the productivity  
707 gains from AI.

708 This reallocation also reverses the steady-state comparison of factor prices: en-  
709 dogenous human capital adjustment transforms the negative direct effect of AI on  
710 the wage rate into a positive net effect, and the positive direct effect on capital  
711 returns into a negative net effect.

## 712 *6.2 Distributional Implications*

713 The findings above underscore the importance of accounting for human capital ad-  
714 justments when assessing the aggregate impact of AI, as households actively adapt  
715 to a rapidly evolving labor market. When it comes to economic inequality, endoge-  
716 nously adjusting human capital plays an even more significant role.

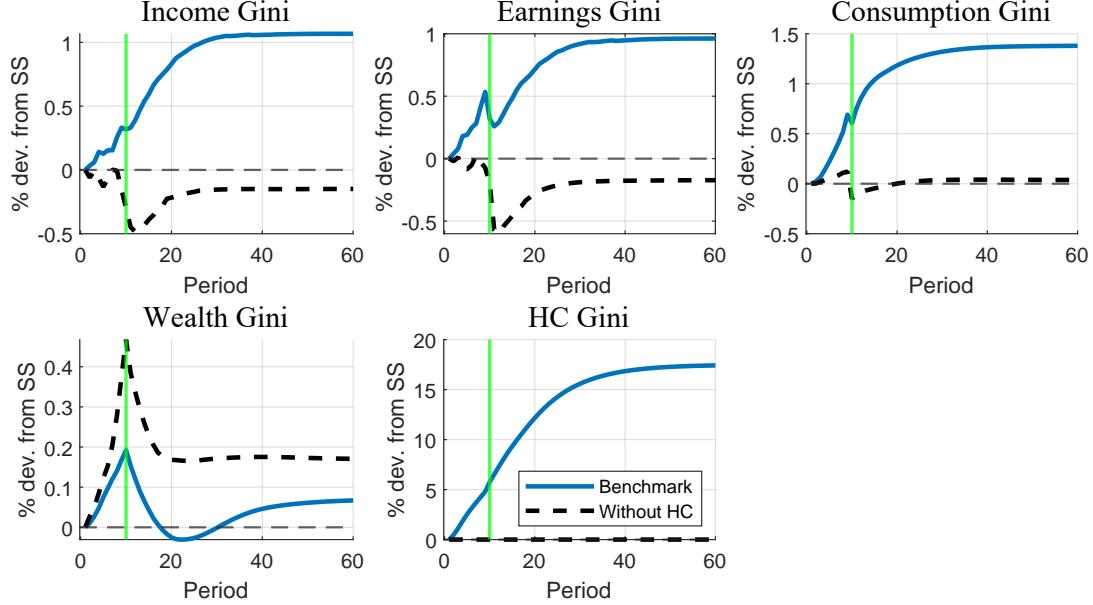

717 Figure 7 shows the transition paths of Gini coefficients for earnings (labor in-  
718 come), total income (capital and labor income), consumption, wealth (asset hold-  
719 ings), and human capital. The black dashed lines represent results from the No-HC  
720 model, capturing the direct impact of AI without human capital adjustment. In  
721 contrast, the blue solid lines reflect the benchmark model, where human capital re-  
722 sponds endogenously to both anticipated and realized changes in the skill premium  
723 induced by AI.

### 724 **6.2.1 Income, earnings, and consumption inequalities**

725 The comparison of transition paths between the No-HC model and the benchmark  
726 model reveals that endogenous human capital adjustments fundamentally alter the  
727 impact of AI on income, earnings, and consumption inequalities.

728 **AI's direct impacts:** Without any human capital adjustments, AI's impact on  
729 inequalities is primarily driven by productivity gains in the low and high sectors  
730 – 7.5% and 5%, respectively. As a result, there is little direct impact on income  
731 and earnings Gini coefficients in anticipation of AI before period 10. After AI is  
732 implemented, both income and earnings inequality decline: higher labor productivity  
733 raises earnings in the low sector, while wage declines in the middle sector compress

Figure 7: Transition Path of Inequality Measures: Benchmark vs. No HC Models.

Note: The transition paths of inequality measures: benchmark vs. No HC models. The x-axis represents years, and the y-axis shows the percentage deviation from the initial steady state. AI introduction is assumed to occur in period 10. The No HC model is an economy in which workers maintain their initial steady-state level of human capital throughout the AI implementation until the new steady state is reached.

734 the distribution. Consumption inequality remains largely unchanged throughout  
735 the transition.

736 **Effects of AI-induced human capital adjustments:** Allowing human capital  
737 to adjust endogenously, however, leads to pronounced job polarization, as shown in  
738 Section 5.2. Households who would have qualified for middle-sector jobs now tran-  
739 sition to either the low or high sector. Those moving to the low sector see reduced  
740 labor earnings, while those shifting to the high sector enjoy increased earnings. This  
741 polarization drives up earnings and income inequality, both before and after AI is  
742 implemented. As income disparities widen, consumption inequality also increases.

#### 743 6.2.2 Wealth inequality

744 In stark contrast to the effects on income and earnings inequality, allowing for en-  
745 dogenous human capital adjustment mitigates the negative direct impact of AI on  
746 wealth inequality. While AI's direct effect would otherwise widen disparities, human  
747 capital responses help dampen the increase in wealth inequality, underscoring the  
748 stabilizing role of human capital adjustments in the wealth distribution.

749 **AI's direct impacts:** Without any human capital adjustment, AI's impact on  
750 households' saving works purely through income effect. In both the low and high  
751 sectors, households reduce their savings in anticipation of AI, expecting higher life-  
752 time labor income. After AI is implemented at period 10, their savings increase  
753 alongside rising labor incomes. In contrast, households in the middle sector, antic-

754 ipating a negative income effect from AI due to a lower wage rate, increase their  
755 savings prior to period 10. Once AI is introduced and the wage rate recovers,  
756 middle-sector households reduce their savings.

757 These shifts in sectoral saving patterns sharply increase wealth inequality before  
758 period 10, as low-sector households – typically the least wealthy – reduce their asset  
759 holdings. After AI is implemented and saving rates in the low sector recover, the  
760 wealth Gini coefficient declines from its peak and stabilizes at a level about 0.2%  
761 higher than its initial steady state.

762 **Effects of AI-induced human capital adjustments:** Endogenous human cap-  
763 ital responses introduce an additional channel. AI-induced changes in the skill  
764 premium motivate more households in the middle and high sectors to undertake  
765 full-time training, either to move into or remain in the high sector. This extensive  
766 margin adjustment requires these households to forgo labor income and rely on their  
767 assets to finance consumption, thus reducing their ability to accumulate additional  
768 savings during the transition. Meanwhile, low-sector households reduce their full-  
769 time investment in human capital, freeing up resources to save more. As a result,  
770 this endogenous response of human capital dampens the rise in wealth inequality  
771 that would otherwise occur, helping to stabilize the wealth distribution even as AI  
772 reshapes the labor market.

773 I cannot really explain well why the wealth gini in the benchmark model is lower  
774 than in the No-HC-model, please help to improve this part.

## 775 7 Conclusion

776 Recent studies on AI suggest that advancements are likely to reduce demand for  
777 junior-level positions in high-skill industries while increasing the need for roles fo-  
778 cused on advanced decision-making and AI oversight. We demonstrate how human  
779 capital investments are expected to adapt in response to these shifts in skill demand,  
780 highlighting the importance of accounting for these human capital responses when  
781 assessing AI’s economic impact.

782 Our work points to several promising directions for future research on the eco-  
783 nomic impacts of AI. First, while general equilibrium effects—such as wage and  
784 capital return adjustments—have a limited role in our model, further research could  
785 examine how these effects might vary under different economic conditions or policy  
786 environments. Second, if governments implement redistribution policies to address  
787 AI-induced inequality, understanding how these policies influence human capital  
788 accumulation, and thus their effectiveness, would be valuable. Finally, our model  
789 assumes households have perfect foresight when making human capital investments.  
790 Relaxing this assumption could reveal new insights into the economic trajectory of  
791 AI advancements and offer important policy implications.

## 889        A Household Decision Rule Cutoffs

### 890        A.1 Additional cutoffs formulae for households

$$\bar{z}_{non}^M(a) := \frac{(\exp(\frac{\chi_n}{1+\beta}) - 1)[(1+r)a + \frac{w'z'}{1+r'}]}{w} \quad (\text{A.1})$$

$$\bar{z}_{slow}^M(a) := \frac{(\exp(\frac{\chi_n - \chi_e e_H}{1+\beta}) - 1)[(1+r)a + \frac{w'z'(1+\lambda)}{1+r'}] + \lambda \frac{w'z'}{1+r'}}{w} \quad (\text{A.2})$$

$$\bar{z}_{fast}^M(a) := \frac{(\exp(\frac{\chi_n}{1+\beta}) - 1)[(1+r)a + \frac{w'z'(1+\lambda)}{1+r'}]}{w} \quad (\text{A.3})$$

$$\bar{z}_{fast}^M(a) := \frac{\left\{ \lambda \left[ \exp(\frac{\chi_e e_L}{1+\beta}) - 1 \right]^{-1} - 1 \right\} \frac{w'z'}{1+r'} - (1+r)a}{w} \quad (\text{A.4})$$

$$\bar{z}_{non}^H(a) := \frac{(\exp(\frac{\chi_n}{1+\beta}) - 1)[(1+r)a + \frac{w'z'(1+\lambda)}{1+r'}]}{w} \quad (\text{A.5})$$

### 891        A.2 Parameter restrictions for cutoffs ranking

892        To guarantee that  $(n = 0, e = e_H)$  dominates  $(n = 0, e = 0)$ , we need a lower bound  
 893        for  $\lambda$ . The slow learners prefer  $(n = 0, e = e_H)$  if and only if

$$(1 + \beta) \ln c(n = 0, e = e_H) - \chi_e e_H \geq (1 + \beta) \ln c(n = 0, e = 0)$$

894 or equivalently:

$$\lambda \geq \underline{\lambda}_1 := \frac{(1+r)a + \frac{w'z'}{1+r'}}{\frac{w'z'}{1+r'}} \left( 1 - \frac{1}{\exp(\frac{\chi_e e_H}{1+\beta})} \right) \text{ if } h < h_M \frac{1}{1-\delta} \quad (\text{A.6})$$

$$\lambda \geq \underline{\lambda}_3 := \frac{(1+r)a + \frac{w'z'}{1+r'}}{\frac{w'z'}{1+r'}} \left( \exp(\frac{\chi_e e_H}{1+\beta}) - 1 \right) \text{ if } h \geq h_M \frac{1}{1-\delta} \quad (\text{A.7})$$

895 To avoid  $(n = 1, e = e_L)$  from being a dominated choice, we need another lower  
896 bound for  $\lambda$ . To see it, recall that  $(n = 1, e = 0)$  is better than  $(n = 1, e = e_L)$   
897 if  $z > \bar{z}_{fast}$ , and  $(n = 1, e = e_L)$  is better than  $(n = 0, e = e_L)$  if  $z > \underline{z}_{fast}$ .  
898  $(n = 1, e = e_L)$  is therefore the best choice over the interval  $(\underline{z}_{fast}, \bar{z}_{fast})$ . For such an  
899 interval to exist, it must be the case that when  $z = \underline{z}_{fast}$ ,  $z < \bar{z}_{fast}$ .  $z = \underline{z}_{fast}$  means  
900 that the fast learners are indifferent between  $(n = 1, e = e_L)$  and  $(n = 0, e = e_L)$  so  
901 that

$$(1+r)a + wzx(h) + \frac{w'z'}{1+r'} = \exp(\frac{\chi_n}{1+\beta}) \left[ (1+r)a + \frac{w'z'}{1+r'} \right] \text{ if } h < h_M \frac{1}{1-\delta} \quad (\text{A.8})$$

$$(1+r)a + wzx(h) + \frac{w'z'(1+\lambda)}{1+r'} = \exp(\frac{\chi_n}{1+\beta}) \left[ (1+r)a + \frac{w'z'(1+\lambda)}{1+r'} \right] \text{ if } h \geq h_M \frac{1}{1-\delta} \quad (\text{A.9})$$

902 For the fast learners to prefer  $(n = 1, e = e_L)$  over  $(n = 1, e = 0)$ , we need

$$(1+\beta) \ln \frac{c(n=1, e=e_L)}{c(n=1, e=0)} \geq \chi_e e_L \quad (\text{A.10})$$

903 If  $h < h_M \frac{1}{1-\delta}$ , inequality (A.10) is:

$$(1+\beta) \ln \frac{(1+r)a + wzx(h) + \frac{w'z'}{1+r'}}{(1+r)a + wzx(h) + \frac{w'z'(1-\lambda)}{1+r'}} \geq \chi_e e_L$$

904 Evaluating the left-hand-side at  $z = \underline{z}_{fast}$  yields:

$$\lambda \geq \underline{\lambda}_2 := \frac{(1+r)a + \frac{w'z'}{1+r'}}{\frac{w'z'}{1+r'}} \left( 1 - \frac{1}{\exp(\frac{\chi_e e_L}{1+\beta})} \right) \exp(\frac{\chi_n}{1+\beta}) \quad (\text{A.11})$$

905 If  $h > h_M \frac{1}{1-\delta}$ , inequality (A.10) is:

$$(1+\beta) \ln \frac{(1+r)a + wzx(h) + \frac{w'z'(1+\lambda)}{1+r'}}{(1+r)a + wzx(h) + \frac{w'z'}{1+r'}} \geq \chi_e e_L$$

906 Evaluating the left-hand-side at  $z = \underline{z}_{fast}$  yields:

$$\lambda \geq \underline{\lambda}_4 := \frac{(1+r)a + \frac{w'z'}{1+r'}}{\frac{w'z'}{1+r'}} \frac{\left(\exp\left(\frac{\chi_e e_L}{1+\beta}\right) - 1\right) \exp\left(\frac{\chi_n}{1+\beta}\right)}{\exp\left(\frac{\chi_e e_L}{1+\beta}\right) + \exp\left(\frac{\chi_n}{1+\beta}\right) - \exp\left(\frac{\chi_e e_L + \chi_n}{1+\beta}\right)} \quad (\text{A.12})$$

907 We have that  $\underline{\lambda}_1 > \underline{\lambda}_2$  and  $\underline{\lambda}_3 > \underline{\lambda}_4$  if

$$\exp\left(\frac{\chi_e e_H}{1+\beta}\right) > \frac{\exp\left(\frac{\chi_e e_L}{1+\beta}\right)}{\exp\left(\frac{\chi_e e_L}{1+\beta}\right) + \exp\left(\frac{\chi_n}{1+\beta}\right) - \exp\left(\frac{\chi_e e_L + \chi_n}{1+\beta}\right)} \quad (\text{A.13})$$

908 Therefore, the inequality above implies that the conditions (A.6) and (A.7) are  
909 sufficient for the conditions (A.11) and (A.12). Furthermore,  $\lambda_3 \geq \lambda_1$  so that the  
910 condition (A.7) is sufficient for the condition (A.6).

911 We can then conclude that the conditions (A.7) and (A.13) are sufficient for  
912 1) the slower learners always prefers  $(n = 0, e = e_H)$  over  $(n = 0, e = 0)$ , and 2)  
913  $\bar{z}_{fast} > \underline{z}_{fast}$ , i.e., there exists state space where  $(n = 1, e = e_L)$  is optimal.

### 914 A.3 Other cutoffs ranking for the two-period Model

915 For the fast learners, their cutoffs rank as follows

$$\frac{\bar{z}_{fast}^L(a)}{1-\lambda} > \bar{z}_{fast}^L(a) > \bar{z}_{fast}^M(a) > \frac{\bar{z}_{fast}^M(a)}{1+\lambda} \quad (\text{A.14})$$

$$\frac{\underline{z}_{fast}^L(a)}{1-\lambda} > \underline{z}_{fast}^M(a) > \underline{z}_{fast}^L(a) > \frac{\underline{z}_{fast}^M(a)}{1+\lambda} \quad (\text{A.15})$$

916 For the slow learners, the rank of their cutoffs is

$$\frac{\bar{z}_{slow}^L(a)}{1-\lambda} > \bar{z}_{slow}^M(a) > \bar{z}_{slow}^L(a) > \frac{\bar{z}_{slow}^M(a)}{1+\lambda} \quad (\text{A.16})$$

917 For the non-learners, the rank of their cutoffs is

$$\frac{\bar{z}_{non}^L(a)}{1-\lambda} > \bar{z}_{non}^M(a) > \frac{\bar{z}_{non}^H(a)}{1+\lambda} > \frac{\bar{z}_{non}^M(a)}{1+\lambda} \quad (\text{A.17})$$

$$\bar{z}_{non}^M(a) > \bar{z}_{non}^L(a) \quad (\text{A.18})$$

## 918 B Proof of Proposition

### 919 B.1 Proof of Proposition 2

920 The derivative of saving with respect to  $t$  is

$$\frac{\partial a'^*}{\partial t}(x, a; t) = -\frac{x\mu}{1+\beta} + \frac{x^2\Sigma}{\beta} \frac{t[2(x+a) + tx\mu]}{[(x+a) + tx\mu]^2}. \quad (\text{B.1})$$

921 The total effect of on-job-training on saving is

$$\Delta_{\text{on-job}}(x, a; t) = a'^*(x, a; t) - a'^*(x, a; 1) = \int_1^t \frac{\partial a'^*}{\partial u}(x, a; u) du. \quad (\text{B.2})$$

922 Define

$$F(x, a; u) \equiv x \frac{u[2(x + a) + ux\mu]}{[(x + a) + ux\mu]^2}, \quad \bar{F}(x, a; t) \equiv \frac{1}{t-1} \int_1^t F(x, a; u) du.$$

923 Then equation (B.2) can be written as

$$\Delta_{\text{on-job}}(x, a; t) = x(t-1) \left[ \frac{\Sigma}{\beta} \bar{F}(x, a; t) - \frac{\mu}{1+\beta} \right].$$

924 Differentiating  $F(x, a; u)$  with respect to  $x$  gives

$$\frac{\partial F(x, a; u)}{\partial x} = \frac{2u a (a + x)}{(a + (1 + u\mu)x)^3} > 0,$$

925 so  $\bar{F}(x, a; t)$  is strictly increasing in  $x$ .

926 The sign of  $\Delta_{\text{on-job}}(x, a; t)$  is governed by

$$S(x, a; t) \equiv \frac{\Sigma}{\beta} \bar{F}(x, a; t) - \frac{\mu}{1+\beta}.$$

927 Because  $\bar{F}(x, a; t)$  is strictly increasing,  $S(x, a; t)$  increases monotonically with  $x$ .

928 For  $x \rightarrow 0$ ,  $F(x, a; u) \rightarrow 0$  and  $\bar{F}(x, a; t) \rightarrow 0$  so that  $S(x, a; t) \rightarrow -\frac{\mu}{1+\beta} < 0$ ,  
929 implying  $\Delta_{\text{on-job}}(x, a; t) < 0$  for small  $x$ .

930 For  $x \rightarrow \infty$ ,  $F(x, a; u) \rightarrow \frac{u(2+u\mu)}{(1+u\mu)^2}$  and  $\bar{F}(x, a; t) \rightarrow \bar{F}_\infty(t) \equiv \frac{1}{t-1} \int_1^t \frac{u(2+u\mu)}{(1+u\mu)^2} du$ . If

$$\frac{\Sigma}{\mu} > \underline{\sigma}(t) \equiv \frac{\beta}{1+\beta} \frac{1}{\bar{F}_\infty(t)} \quad (\text{B.3})$$

931 then  $S(x, a; t) > 0$  for sufficiently large  $x$ , and hence  $\Delta_{\text{on-job}}(x, a; t) > 0$ .

932 If idiosyncratic risk is large enough, i.e., condition (B.3) is satisfied, there exists  
933 a unique threshold  $x^*(t)$  at which the sign flips:

$$\Delta_{\text{on-job}}(x, a; t) < 0 \text{ for } x < x^*(a, t), \quad \Delta_{\text{on-job}}(x, a; t) > 0 \text{ for } x > x^*(a, t).$$

## 934 B.2 Proof of Proposition 3

935 Denote

$$G(x, a; t) \equiv \frac{t^2 x^2}{(a + x + tx\mu)(a + tx\mu)}$$

936 the net additional effect of full-time training on saving can be rewritten as

$$\Delta_H(x, a; t) \equiv x \left[ -\frac{\beta}{1+\beta} + \frac{\Sigma}{\beta} G(x, a; t) \right]$$

937 Differentiating  $G(x, a; t)$  with respect to  $x$  gives

$$\frac{\partial G(x, a; t)}{\partial x} = \frac{t^2 x a (2tx\mu + 2a + x)}{(a + tx\mu)^2 (a + x + tx\mu)^2} > 0,$$

938 so  $G(x, a; t)$  is strictly increasing in  $x$ .

939 The limits of  $G(x, a; t)$  are:

$$G(x, a; t) \rightarrow 0 \quad (x \rightarrow 0),$$

940

$$G(x, a; t) \rightarrow G_\infty(t) \equiv \frac{t}{\mu(1+t\mu)} \quad (x \rightarrow \infty),$$

941 Therefore,  $G(x, a; t) < G_\infty(t)$  for any  $x$ .

942 If

$$\frac{\Sigma}{\beta} G_\infty(t) < \frac{\beta}{1+\beta}, \text{ i.e. } \frac{\Sigma}{\mu} < \bar{\sigma}(t) \equiv \frac{\beta^2}{1+\beta} \left( \frac{1}{t} + \mu \right). \quad (\text{B.4})$$

943 Then  $\Delta_H(x, a; t) < x[-\frac{\beta}{1+\beta} + \frac{\Sigma}{\beta} G_\infty(t)] < 0$  for any  $x$ .

944 Furthermore, with some tedious algebra, we can show that for any  $x$

$$G(x, a; t) + x \frac{\partial G(x, a; t)}{\partial x} < G_\infty(t)$$

945 Hence, the inequality (B.4) also implies that

$$\frac{\partial \Delta_H(x, a; t)}{\partial x} = \frac{\Sigma}{\beta} [G(x, a; t) + x \frac{\partial G(x, a; t)}{\partial x}] - \frac{\beta}{1+\beta} < \frac{\Sigma}{\beta} G_\infty(t) - \frac{\beta}{1+\beta} < 0. \quad (\text{B.5})$$

### 946 B.3 Proof of Proposition 4

947 The relevant upper bounds of  $z$  for positive human capital investment are functions  
948 of  $\gamma$  (to the first order approximation):

$$\begin{aligned} \bar{z}_{slow}^L(a; \gamma) &= \bar{z}_{slow}^L(a; \gamma = 0) - \gamma \lambda \frac{w' z'}{w(1+r')} \\ \bar{z}_{fast}^L(a; \gamma) &= \bar{z}_{fast}^L(a; \gamma = 0) - \gamma \lambda \frac{w' z'}{w(1+r')} \frac{\exp(\frac{\chi_e e_L}{1+\beta})}{\exp(\frac{\chi_e e_L}{1+\beta}) - 1} \\ \bar{z}_{slow}^M(a; \gamma) &= \bar{z}_{slow}^M(a; \gamma = 0) + \gamma \lambda \frac{w' z'}{w(1+r')} \exp\left(\frac{\chi_n - \chi_e e_H}{1+\beta}\right) \\ \bar{z}_{fast}^M(a; \gamma) &= \bar{z}_{fast}^M(a; \gamma = 0) + \gamma \lambda \frac{w' z'}{w(1+r')} \frac{1}{\exp(\frac{\chi_e e_L}{1+\beta}) - 1} \end{aligned}$$

949 Therefore, an anticipated AI shock,  $\gamma > 0$  makes those with  $h < h_M \frac{1}{1-\delta}$  invest less  
 950 human capital and those with  $h > h_M \frac{1}{1-\delta}$  invest more human capital.

951 *B.4 Proof of Proposition 5*

$$\Delta_{\text{on-job}}(x, a; t) = a'^*(x, a; t) - a'^*(x, a; 1) = \int_1^t \frac{\partial a'^*}{\partial u}(x, a; u) du.$$

952 differentiating with respect to  $t$  gives

$$\frac{d\Delta_{\text{on-job}}(x, a; t)}{dt} = \frac{\partial a'^*}{\partial t}(x, a; t)$$

953 Since

$$\frac{\partial^2 a'^*(x, a; t)}{\partial t^2} = \frac{\partial}{\partial t} \left( -\frac{x\mu}{1+\beta} + \frac{x^2\Sigma}{\beta} \frac{t[2(x+a)+tx\mu]}{[(x+a)+tx\mu]^2} \right) = \frac{2x^2\Sigma(a+x)^2}{\beta(a+x+tx\mu)^3} > 0. \quad (\text{B.6})$$

954 The slope  $\frac{\partial a'^*}{\partial t}(x, a; t)$  is strictly increasing in  $t$ . Hence  $\Delta_{\text{on-job}}(x, a; t)$  is convex in  $t$ .

$$\Delta_H(x, a; t) = x \left[ -\frac{\beta}{1+\beta} + \frac{\Sigma}{\beta} G(x, a; t) \right] \text{ with } G(x, a; t) = \frac{t^2 x^2}{(a+x+tx\mu)(a+tx\mu)}$$

955 Differentiating  $G(x, a; t)$  with respect to  $t$  gives

$$\frac{\partial G(x, a; t)}{\partial t} = \frac{tx^2(2a^2 + 2atx\mu + 2ax + \mu tx^2)}{(a+tx\mu)^2(a+x+tx\mu)^2} > 0,$$

956 so  $G(x, a; t)$  is strictly increasing in  $t$ , and so is  $\Delta_H(x, a; t)$ .

957 We now consider the comparison between  $\Delta_{\text{on-job}}(x, a; t)$  and  $\Delta_{\text{on-job}}(x, a; t')$  for  $t' >$   
 958  $t$ . Given  $x$  and  $a$ , define

$$f(t) \equiv \frac{\partial a'^*}{\partial t}(x, a; t).$$

959 so  $f'(t) > 0$ , i.e.  $f(t)$  is strictly increasing in  $t$ .

960 **Case 1:**  $1 < t < t'$

961 Suppose  $\Delta_{\text{on-job}}(x, a; t) > 0$ . Then

$$\Delta_{\text{on-job}}(x, a; t) = \int_1^t f(u) du > 0.$$

962 Since  $f$  is increasing,

$$f(u) \leq f(t) \quad \text{for all } u \in [1, t],$$

963 which implies

$$\Delta_{\text{on-job}}(x, a; t) = \int_1^t f(u) du \leq (t-1) f(t).$$

964 Because  $t > 1$ , the inequality  $\Delta_{\text{on-job}}(x, a; t) > 0$  forces  $f(t) > 0$ .

965 Now for any  $t' > t$ ,

$$f(u) \geq f(t) > 0 \quad \text{for all } u \in [t, t'],$$

966 and therefore

$$\Delta_{\text{on-job}}(x, a; t') - \Delta_{\text{on-job}}(x, a; t) = \int_t^{t'} f(u) du > 0.$$

967 We then have that:

$$1 < t < t', \Delta_{\text{on-job}}(x, a; t) > 0 \implies \Delta_{\text{on-job}}(x, a; t') > \Delta_{\text{on-job}}(x, a; t) \quad (\text{B.7})$$

968 That is, once  $\Delta_{\text{on-job}}(x, a; t)$  becomes positive for  $t > 1$ , it is strictly increasing in  $t$   
969 thereafter.

970 **Case 2:**  $t < t' < 1$

971 For  $t < 1$ ,

$$\Delta_{\text{on-job}}(x, a; t) = \int_1^t f(u) du = - \int_t^1 f(u) du.$$

972 Suppose  $\Delta_{\text{on-job}}(x, a; t) > 0$ . Then

$$-\int_t^1 f(u) du > 0 \implies \int_t^1 f(u) du < 0.$$

973 Since  $f$  is increasing

$$f(u) \geq f(t) \quad \text{for all } u \in [t, 1],$$

974 which implies

$$\int_t^1 f(u) du \geq (1-t) f(t).$$

975 Because  $t < 1$ , the inequality  $\Delta_{\text{on-job}}(x, a; t) > 0$  forces  $f(t) < 0$ .

976 Consider

$$\Delta_{\text{on-job}}(x, a; t') - \Delta_{\text{on-job}}(x, a; t) = \int_t^{t'} f(u) du$$

977 If  $f(u) < 0$  for all  $u \in [t, t']$ , then  $\int_t^{t'} f(u) du < 0$ .

978 If there exists some  $t_s \in [t, t']$  such that  $f(t_s) = 0$ , so  $f(u) < 0$  for  $u < t_s$  and  
979  $f(u) > 0$  for  $u > t_s$ . Then  $f(u) > 0$  for  $u \in [t', 1]$ . Hence,

$$\int_{t'}^1 f(u) du > 0$$

980 This implies that

$$\Delta_{\text{on-job}}(x, a; t') = - \int_{t'}^1 f(u) du < 0$$

981 Together with the inequality  $\Delta_{\text{on-job}}(x, a; t) > 0$ , we have that

$$\Delta_{\text{on-job}}(x, a; t') < \Delta_{\text{on-job}}(x, a; t)$$

982 We then have that

$$t < t' < 1, \Delta_{\text{on-job}}(x, a; t) > 0 \implies \Delta_{\text{on-job}}(x, a; t') < \Delta_{\text{on-job}}(x, a; t). \quad (\text{B.8})$$

983 Thus, for  $t < 1$ , whenever  $\Delta_{\text{on-job}}(x, a; t) > 0$ , increasing  $t$  toward 0 makes  $\Delta_{\text{on-job}}$   
984 strictly decrease.

## 985 C Computational Procedure for the Quantitative Model

### 986 C.1 Steady-state Equilibrium

987 In the steady-state, the measure of households,  $\mu(a, h, x)$ , and the factor prices are  
988 time-invariant. We find a time-invariant distribution  $\mu$ . We compute the house-  
989 holds' value functions and the decisions rules, and the time-invariant measure of the  
990 households. We take the following steps:

- 991 1. We choose the number of grid for the risk-free asset,  $a$ , human capital,  $h$ , and  
992 the idiosyncratic labor productivity,  $x$ . We set  $N_a = 151$ ,  $N_h = 151$ , and  
993  $N_x = 9$  where  $N$  denotes the number of grid for each variable. To better  
994 incorporate the saving decisions of households near the borrowing constraint,  
995 we assign more points to the lower range of the asset and human capital.
- 996 2. Productivity  $x$  is equally distributed on the range  $[-3\sigma_x/\sqrt{1-\rho_x^2}, \sqrt{1-\rho_x^2}]$ . As shown  
997 in the paper, we construct the transition probability matrix  $\pi(x'|x)$  of the  
998 idiosyncratic labor productivity.
- 999 3. Given the values of parameters, we find the value functions for each state  
1000  $(a, h, x)$ . We also obtain the decision rules: savings  $a'(a, h, x)$ , and  $h'(a, h, x)$ .  
1001 The computation steps are as follow:
- 1002 4. After obtaining the value functions and the decision rules, we compute the  
1003 time-invariant distribution  $\mu(a, h, x)$ .
- 1004 5. If the variables of interest are close to the targeted values, we have found the  
1005 steady-state. If not, we choose the new parameters and redo the above steps.

1006    *C.2 Transition Dynamics*

1007    We incorporate the transition path from the status quo to the new steady state. We  
1008    describe the steps below.

- 1009    1. We obtain the initial steady state and the new steady state.
- 1010    2. We assume that the economy arrives at the new steady state at time  $T$ . We  
1011    set the  $T$  to 100. The unit of time is a year.
- 1012    3. We initialize the capital-labor ratio  $\{K_t/L_t\}_{t=2}^{T-1}$  and obtain the associated  
1013    factor prices  $\{r_t, w_t\}_{t=2}^{T-1}$ .
- 1014    4. As we know the value functions at time  $T$ , we can obtain the value functions  
1015    and the decision rules in the transition path from  $t = T - 1$  to 1.
- 1016    5. We compute the measures  $\{\mu_t\}_{t=2}^T$  with the measures at the initial steady state  
1017    and the decision rules in the transition path.
- 1018    6. We obtain the aggregate variables in the transition path with the decision rules  
1019    and the distribution measures.
- 1020    7. We compare the assumed paths of capital and the effective labor with the  
1021    updated ones. If the absolute difference between them in each period is close  
1022    enough, we obtain the converged transition path. Otherwise, we assume new  
1023    capital-labor ratio and go back to 3.

1024    **D Investigating the GE channel of AI's impact**

1025    **Redistribution versus general equilibrium effects:** The effects of human cap-  
1026    ital adjustments on AI's aggregate impacts operate through two primary channels:  
1027    the *redistribution channel*, which reallocates households across skill sectors, and the  
1028    *general equilibrium (GE) channel*, which operates through changes in wages and  
1029    capital returns. We now assess the relative importance of these channels in shaping  
1030    economic outcomes.

1031    Figure ?? compares the transition dynamics between scenarios with and without  
1032    human capital adjustments, while holding wages and capital returns fixed at their  
1033    initial steady-state levels to eliminate GE effects. We refer to the former as the  
1034    "PE Model" and the latter as the "No-HC PE Model." The difference between the  
1035    solid blue line and the dashed red line isolates the effect of redistribution channel.  
1036    Comparing this difference to the gap between the benchmark model and the No  
1037    HC model in Figure 6 enables us to evaluate the importance of the redistribution  
1038    channel relative to the GE channel. Two key observations emerge.

1039    First, the *redistribution channel* alone accounts for all the *qualitative effects* of  
1040    human capital adjustments on AI's aggregate impacts. Redistribution of human

Figure 8: Caption  
Consumption

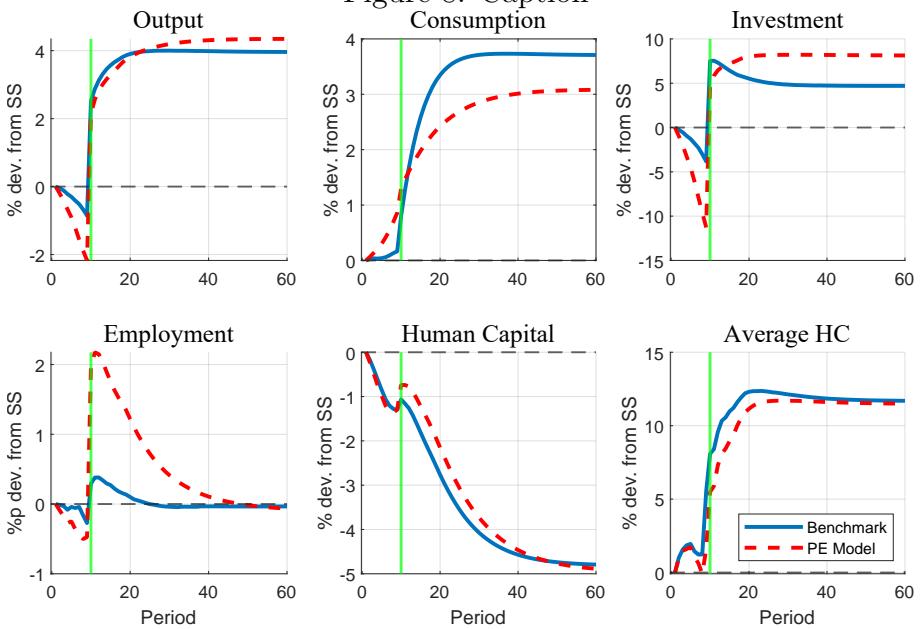

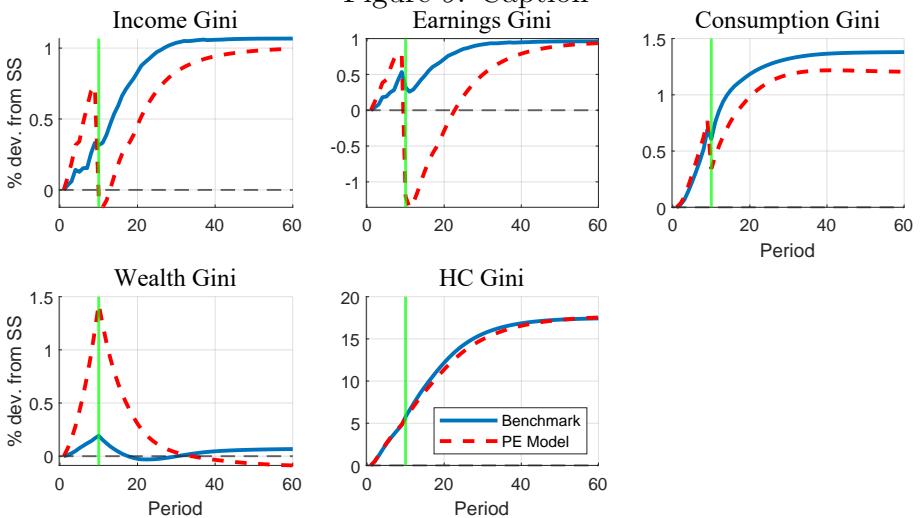

Figure 9: Caption  
Earnings Gini

1041 capital increases consumption, even before AI implementation, as more households  
1042 shift to the high sector. It also reduces investment by mitigating precautionary  
1043 savings and lowers employment as middle-sector workers leave the labor market  
1044 to invest in human capital. In the long run, redistribution amplifies AI's positive  
1045 impact on output by reallocating more workers to sectors that benefit most from AI  
1046 advancements.

1047 Second, the *GE channel* primarily affects the *quantitative magnitude* of human  
1048 capital adjustments' impact on AI's aggregate outcomes. When the GE channel is  
1049 included, the differences in output, consumption, and employment between models  
1050 with and without human capital adjustments are smaller compared to when the  
1051 GE channel is excluded. In contrast, and somewhat unexpectedly, the difference in  
1052 investment is larger when the GE channel is included. This indicates that allowing  
1053 capital returns to adjust amplifies the impact of human capital accumulation on  
1054 how household savings respond to AI.

1055 When the *GE channel* is active (Figure ??), AI reduces the wealth Gini, but  
1056 the *redistribution channel* moderates this effect. However, when the *GE channel*  
1057 is disabled (Figure ??), AI increases wealth inequality in the long run without the  
1058 *redistribution channel* from human capital adjustment. In contrast, with the *redis-*  
1059 *tribution channel* active, AI reduces wealth inequality.

1060 These observations lead to two key conclusions:

1061 First, the *redistribution channel* alone introduces a qualitative shift in AI's long-  
1062 run impact on the wealth Gini (as shown in Figure ??).

1063 Second, the *GE channel*, when combined with human capital adjustment, qual-  
1064 itatively alters the effect of anticipating AI on the wealth Gini (as shown by com-  
1065 paring the blue lines in Figures ?? and ??).

1066 **Policy implications:** The impact of human capital adjustments on AI's distribu-  
1067 tional outcomes, along with the roles of the *redistribution channel* and *GE channel*,  
1068 provides valuable insights for policy discussions on how to address the challenges  
1069 posed by AI shocks.

1070 In particular, government interventions aimed at stabilizing wages in response  
1071 to AI-induced economic shocks may unintentionally worsen wealth inequality. Our  
1072 analysis indicates that if wages are prevented from adjusting to reflect productiv-  
1073 ity differences, this distorts households' incentives to adjust their human capital  
1074 and precautionary savings—both of which play a critical role in mitigating wealth  
1075 inequality.
